By $M$-matrix theory, inequality techniques, and Lyapunov functional method, certain sufficient conditions are obtained to ensure the existence, uniqueness, and global exponential stability of periodic solution for a new type of high-order BAM neural networks with continuously distributed delays and impulses. These novel conditions extend and improve some previously known results in the literature. Finally, an illustrative example and its numerical simulation are given to show the feasibility and correctness of the derived criteria.

1. Introduction

As is well known, during the hardware implementation of neural networks, time delays are inevitable due to finite switching speeds of the amplifiers and communication time, which may bring about complex influence on the system such as oscillation and instability [1, 2]. On the other hand, impulsive effects wildly exist in many realistic networks [3, 4], which may be caused by witching phenomenon, sudden changes, or other unexpected noise. Therefore, it is more appropriate to consider delay and impulsive effects when modeling neural networks, and many researches on various kinds of neural networks with delays, impulses, or both of them have been available [5–12]. (See Figures 1(a), 1(b), and 1(c)).

Bidirectional associative memory (BAM) neural networks, as an extension of the unidirectional autoassociator of Hofield neural network [13], was firstly introduced by Kosko [14]. Due to its wide application in pattern recognition, associative memory, image, and signal processing, BAM neural networks with delays and impulses have been extensively studied in the past few decades [15–22]. In addition, it is worth noting that high-order neural networks structures have advantages of stronger storage capacity, faster convergence rate, and higher fault tolerance, and these merits have been successfully used in pattern recognition [23]. Thus, it is important to investigate BAM neural networks with high-order terms, which is called high-order BAM neural networks.

In this paper, we will consider a new type of high-order BAM neural networks with continuously distributed delays and impulses, which can be described by the following integrodifferential equations:

\[
\frac{dx_i(t)}{dt} = -q_i(t)x_i(t) + \sum_{j=1}^{m} c_{ij}(t) \int_{0}^{\infty} K_{ij}(s) f_j(y_j(t-s)) \, ds \\
+ \sum_{j=1}^{m} \sum_{q=1}^{m} s_{ijq}(t) \int_{0}^{\infty} R_{ijq}(s) f_j(y_j(t-s)) f_q(y_q(t-s)) \, ds \\
+ I_i(t), \quad t \neq t_k,
\]

\[
x_i(t_k) = x_i(t_k^-) + \Delta x_i(t_k) = H_{ik}(x_i(t_k^-)),
\]

\[
i = 1, 2, \ldots, n, \quad k \in \mathbb{Z} = \{1, 2, \ldots\},
\]
2. Preliminaries

Notations. Throughout this paper, \( \mathbb{R} \) and \( \mathbb{R}^n \) denote the set of real numbers and \( n \)-dimensional vector space, respectively. The symbol \((\cdot)^T\) denotes the transpose of a vector or a matrix. Take \(|x|_r = (\sum_{i=1}^{n} |x_i|^r)^{1/r}\) with integer \( r \in [1, \infty) \). Clearly, \( \| \cdot \|_1 \), \( \| \cdot \|_2 \) are special cases of \( \| \cdot \|_r \), with \( r = 1, 2 \), respectively, which are used to investigate the dynamics of various kinds of neural networks in [6–8, 10, 12, 15–17, 19, 21, 22, 25–31]. Denote \( C^r = \{ \phi : (-\infty, 0) \to \mathbb{R}^{n+m} \mid \phi(s) \) is continuous for all but at most countable points \( s \in (-\infty, 0) \) and at these points \( s \in (-\infty, 0], \phi(s^-) \) and \( \phi(s^-) \) exist, \( \phi(s) = \phi(s^-) \} \) and define the norm \( \| \phi \|_{\alpha} \) by

\[
\| \phi \|_{\alpha} = \left( \sum_{i=1}^{n} \sup_{s \in (-\infty, 0]} \left| \phi_i(s) \right|^r + \sum_{j=1}^{m} \sup_{s \in (-\infty, 0]} \left| \phi_j(s) \right|^r \right)^{1/r},
\]

where \( \phi = (\phi_1^T, \phi_2^T)^T = (\phi_{i1}, \phi_{i2}, \ldots, \phi_{i,\alpha}, \phi_{j1}, \phi_{j2}, \ldots, \phi_{j,\beta})^T \), and then \( C^r \) is a Banach space with topology of the uniform convergence. In addition, system (1) is supplemented with initial values

\[
\begin{align*}
x_i(s) &= \phi_{i1}(s), & s \in (-\infty, 0], & i = 1, 2, \ldots, n, \\
y_j(s) &= \phi_{j1}(s), & s \in (-\infty, 0], & j = 1, 2, \ldots, m.
\end{align*}
\]

As usual, we have the following assumptions for system (1).

\((S_1)\) Functions \( a_i(t), a_j(t), c_i(t), d_i(t), s_{ij}(t), e_{ij}(t) \), and \( I_i(t), J_j(t) \) are \( \omega \)-periodic and bounded on \([0, +\infty)\) such that \( a_i(t) \geq a_i^- > 0, b_i(t) \geq b_i^- > 0, |c_i(t)| \leq c_i^+, |d_i(t)| \leq d_i^+, |s_{ij}(t)| \leq s_{ij}^+, |e_{ij}(t)| \leq e_{ij}^+, |I_i(t)| \leq I_i, |J_j(t)| \leq J_j \) for \( i, j = 1, 2, \ldots, n \), \( j = 1, 2, \ldots, m \).

\((S_2)\) The activation functions \( g_i(\cdot), g_p(\cdot), f_{ij}(\cdot), \) and \( f_{pq}(\cdot) \) are bounded and Lipschitz continuous on \( \mathbb{R} \); that is, there exist positive numbers \( M_i, M_q, M_p, M_p \) and \( L_i, L_j \) such that

\[
\begin{align*}
\left| f_{ij}(x) \right| &\leq M_i, & \left| f_{pq}(x) \right| &\leq M_q, \\
\left| f_{ij}(x) - f_{ij}(y) \right| &\leq L_i |x - y|, \\
\left| g_i(x) \right| &\leq M_p, & \left| g_p(x) \right| &\leq M_p, \\
\left| g_i(x) - g_i(y) \right| &\leq L_p |x - y|, 
\end{align*}
\]

for \( i, p = 1, 2, \ldots, n, j, q = 1, 2, \ldots, m \) and \( x, y \in \mathbb{R} \).

\((S_3)\) The delay kernel functions \( K_{ij}(\cdot), \bar{K}_{ij}(\cdot), R_{ij}(\cdot), \) and \( \bar{R}_{ij}(\cdot) \) are piecewise continuous functions from \([0, \infty)\) to \([0, \infty)\) and satisfy \( K_{ij}(s) \leq \tilde{\mathcal{K}}(s), \bar{K}_{ij}(s) \leq \tilde{\mathcal{K}}(s), R_{ij}(s) \leq \bar{\mathcal{R}}(s), \) and \( \bar{R}_{ij}(s) \leq \bar{\mathcal{R}}(s) \) for \( s \in [0, \infty) \), \( i, p = 1, 2, \ldots, n, j, q = 1, 2, \ldots, m \), where \( \tilde{\mathcal{K}}(s), \bar{\mathcal{R}}(s) \) satisfy

\[
\begin{align*}
\int_0^\infty \tilde{\mathcal{K}}(s) \, ds &= 1, & \int_0^\infty e^{ts} \tilde{\mathcal{K}}(s) \, ds &< +\infty, \\
\int_0^\infty \bar{\mathcal{R}}(s) \, ds &= 1, & \int_0^\infty e^{ts} \bar{\mathcal{R}}(s) \, ds &< +\infty,
\end{align*}
\]

The rest of this paper is organized as follows. In Section 2, some assumptions, definitions, and important lemmas are given. In Section 3, the main results and some remarks are presented. In Section 4, an example and its numerical simulation are provided. Finally, some conclusions are summarized in Section 5.
(a) State response of the impulse-free system (51)

(b) State response of the impulsive system (51)

(c) Phase plots of system (51) without and with impulses, respectively

Figure 1: It is confirmed that the system (51) has a unique $\pi$-periodic solution. Here $(x_1, y_1)$ and $(x_2, y_2)$ denote two pairs of solution of system (51) with different initial conditions $\phi_1(s) = (-e^{0.01s} + 0.4, e^{0.01s} - 0.4)^T$ and $\phi_2(s) = (0.3, -0.3)^T$ for $s \in [-1, 0]$ and $y = 0.5, t_k - t_{k-1} = \pi, k = 1, 2, \ldots$

in which $\varepsilon$ denotes some positive constant number. For more information on these delay kernels, one can refer to [5, 9, 15, 18, 22].

(S4) $\Omega$ is an $M$-matrix, where $r \geq 1$,

$$
\Omega = \begin{pmatrix}
    rA - (r - 1)G & -L^f\Pi \\
    -L^g\Gamma & rB - (r - 1)F
\end{pmatrix},
$$

where $A = \text{diag}(a_1, a_2, \ldots, a_n)$, $B = \text{diag}(b_1, b_2, \ldots, b_m)$, $G = \text{diag}(G_1, G_2, \ldots, G_n)$, $F = \text{diag}(F_1, F_2, \ldots, F_m)$, $L^g = \text{diag}(L^g_1, L^g_2, \ldots, L^g_n)$, $L^f = \text{diag}(L^f_1, L^f_2, \ldots, L^f_m)$, $G_i = \sum_{j=1}^{m} \sum_{q=1}^{m} (s_{ijq} + s_{ij}^T) M_q^f L_j^f$, $F_j = \sum_{i=1}^{n} \sum_{p=1}^{n} (e_{ijp}^T + e_{jip}) M_p^g L_i^g$.

Definition 1. A function $z(t, \phi) = (x_1(t, \phi), x_2(t, \phi), \ldots)$, $x_n(t, \phi), y_1(t, \phi), y_2(t, \phi), \ldots, y_m(t, \phi))^T \in \mathbb{R}^{n+m}$ is said to be the solution of system (1) with initial condition $\phi \in \mathbb{C}^*$ if the following two conditions are satisfied.

1. $z(t, \phi)$ is piecewise continuous with first kind discontinuity at the points $t_k, k \in \mathbb{Z}$. Moreover, $z(t, \phi)$ is left continuous at each of the discontinuity points. 

2. $z(t, \phi)$ satisfies system (1) for $t \geq 0$ and $z(s) = \phi(s)$ for $s \in (-\infty, 0]$.

Definition 2. The periodic solution $z^*(t, \phi^*)$ of system (1) is said to be globally exponentially stable, if there exist constants
\[ \mathcal{M} \geq 1 \text{ and } \alpha > 0 \text{ such that any other solution } z(t, \phi) \text{ of system } (1) \text{ satisfies} \]
\[ \| z(t, \phi) - z^*(t, \phi^*) \|_r \leq \mathcal{M} e^{-\alpha t} \| \phi - \phi^* \|_\lambda, \quad t \geq 0. \]  

(7)

**Lemma 3** (see [32]). Let \( A \in \mathbb{Z}^{n \times n} \), where \( \mathbb{Z}^{n \times n} \) is a set of \( n \times n \) matrices with nonpositive off-diagonal elements. \( A \) is an \( M \)-matrix if and only if there exists a positive vector \( \lambda = (\lambda_1, \lambda_2, \ldots, \lambda_n)^T \) such that \( \sum_{j=1}^n a_{ij} \lambda_j > 0 \) or \( \sum_{j=1}^n a_{ij} \lambda_j > 0 \).

**Lemma 4.** Assume that assumptions (S1) and (S4) hold; then there exist positive constants \( \epsilon \) and \( \lambda_1, \lambda_2, \ldots, \lambda_{n+m} \) such that
\[ P_i(\epsilon) = \left[ -\epsilon + r a_i^- - (r - 1) G_i \right] \lambda_i \]
\[ - \sum_{j=1}^m \lambda_{m+j} d_{ij}^m L_i^m \int_0^\infty \mathcal{H}(s) e^{\epsilon s} ds \]
\[ - \sum_{j=1}^m \sum_{p=1}^n \lambda_{m+j} (e_{ij^p}^+ + e_{ij^p}^-) M_p^m L_i^m \]
\[ \times \int_0^\infty \mathcal{R}(s) e^{\epsilon s} ds \geq 0, \]  

(8)

\[ Q_j(\epsilon) = \left( -\epsilon + r b_j^- - (r - 1) F_j \right) \lambda_{n+j} \]
\[ - \sum_{i=1}^n \lambda_i c_{ij} L_j^f \int_0^\infty \mathcal{H}(s) e^{\epsilon s} ds \]
\[ - \sum_{i=1}^n \sum_{q=1}^m \lambda_i (s_{ij}^+ + s_{ij}^-) M_i^f L_j^f \]
\[ \times \int_0^\infty \mathcal{R}(s) e^{\epsilon s} ds \geq 0, \]  

for \( i, p = 1, 2, \ldots, n \), \( j, q = 1, 2, \ldots, m \).

**Proof.** Construct the aided functions as follows:
\[ P_i(\theta) = \left[ -\theta_i + r a_i^- - (r - 1) G_i \right] \lambda_i \]
\[ - \sum_{j=1}^m \lambda_{m+j} d_{ij}^m L_i^m \int_0^\infty \mathcal{H}(s) e^{\theta s} ds \]
\[ - \sum_{j=1}^m \sum_{p=1}^n \lambda_{m+j} (e_{ij^p}^+ + e_{ij^p}^-) M_p^m L_i^m \]
\[ \times \int_0^\infty \mathcal{R}(s) e^{\theta s} ds, \]  

(9)

**Lemma 5.** Let the integer \( r \geq 1 \); then the inequality holds as follows:
\[ (n + m)^{(1-r)/r} \sum_{i=1}^{n+m} |z_i| \leq \left( \sum_{i=1}^{n+m} |z_i|^r \right)^{1/r} \]
\[ \text{for all } z = (z_1, z_2, \ldots, z_{n+m}) \in \mathbb{R}^{n+m}. \]

**Proof.** Obviously, the inequality (10) with \( r = 1 \) is trivial. When \( r > 1 \), consider the aided function \( g(x) = x^r, \quad x \geq 0 \). It is claimed that \( g(x) \) is convex since \( g''(x) = r(r-1)x^{r-1} > 0, \quad r > 1 \) for \( x > 0 \). Let \( x = (1/(n + m)) \sum_{i=1}^{n+m} |z_i| \); by Jensen’s inequality, we have
\[ \frac{1}{(n + m)^r} \left( \sum_{i=1}^{n+m} |z_i|^r \right) \leq \frac{1}{n + m} \sum_{i=1}^{n+m} |z_i|^r, \]
which implies that the inequality (10) holds. This completes the proof.

**3. Main Results**

Firstly, let \( z(t, \phi) = (x_1(t, \phi), x_2(t, \phi), \ldots, x_n(t, \phi), \ldots, y_2(t, \phi), y_2(t, \phi), \ldots, y_m(t, \phi))^T \) and \( z(t, \phi) = (x_1(t, \phi), x_2(t, \phi), \ldots, y_2(t, \phi), y_2(t, \phi), y_2(t, \phi), \ldots, y_m(t, \phi))^T \) be any two solutions of system (1) through \( \phi, \psi \in \mathbb{C}^n \), respectively; then we have the following useful lemma.

**Lemma 6.** Under assumptions (S1)–(S4), if the following two conditions hold:
\[ (S_5) \quad H_A(x), E_{jk} \text{ are Lipschitz continuous on } \mathbb{R}; \]
\[ (S_6) \text{ there exist constants } H_k, E_{jk}, k \in \mathbb{Z} \text{ such that} \]
\[ |H_A(x) - H_A(y)| \leq H_k |x - y|, \quad |E_{jk}(x) - E_{jk}(y)| \leq E_{jk} |x - y| \]
\[ \text{for } i = 1, 2, \ldots, n, \quad j, k = 1, 2, \ldots, m, \quad k \in \mathbb{Z} \text{ and } x, y \in \mathbb{R}; \]
\[ (S_7) \text{ there exists } \theta \text{ such that } \ln \eta_k / (t_k - t_{k-1}) \leq \theta < \epsilon, \quad \text{where} \]
\[ t_0 = 0, \quad \eta_k = \max \{1, \max_{1 \leq i \leq n} H_i k, \max_{1 \leq j \leq m} E_{jk} k \}, k \in \mathbb{Z}, \quad \text{and the scalar } \epsilon \text{ is estimated by } (8). \]

Then, the following inequality holds:
\[ \| z(t, \phi) - z(t, \phi') \|_r \leq \mathcal{M} e^{-\alpha t} \| \phi - \phi' \|_\lambda, \quad t \geq 0, \]
\[ \text{where the constants } \mathcal{M} \geq 1 \text{ and } \alpha > 0 \text{ are to be determined later.} \]

**Proof.** To be convenient, let
\[ X_i(t) = |x_i(t, \phi) - x_i(t, \phi')|, \quad i = 1, 2, \ldots, n \]
\[ Y_j(t) = |y_j(t, \phi) - y_j(t, \phi')|, \quad j = 1, 2, \ldots, m. \]

(13)
It follows from ((S1)–(S3)) that

$$D^+ X_i(t)$$

$$\leq -a_i^+ X_i(t) + \sum_{j=1}^m c_{ij}^+ \int_0^\infty \mathcal{H}(s) Y_j(t-s) \, ds$$

$$+ \sum_{j=1}^m \sum_{q=1}^m (s_{ijq}^+ + s_{ijq}^-) M_q^i L_j^i \int_0^\infty \mathcal{R}(s) Y_j(t-s) \, ds,$$

for $$t \geq 0, t \neq t_k, k \in \mathbb{Z}, i = 1, 2, \ldots, n.$$ Similarly, we have

$$D^+ Y_j(t) \leq -b_j^+ Y_j(t) + \sum_{i=1}^m d_{ij}^+ L_i^j \int_0^\infty \mathcal{H}(s) X_i(t-s) \, ds$$

$$+ \sum_{i=1}^m \sum_{p=1}^m (e_{ijp}^+ + e_{ijp}^-) M_p^j L_i^i \int_0^\infty \mathcal{R}(s) X_i(t-s) \, ds,$$

for $$t \geq 0, t \neq t_k, k \in \mathbb{Z}, j = 1, 2, \ldots, m.$$ Also,

$$X_i(t_k + 0) = |H_{ik} X_i(t_k, \phi) - H_{ik} (x_i(t_k, \phi))|$$

$$\leq H_{ik} X_i(t_k), \quad k \in \mathbb{Z}, \ i = 1, 2, \ldots, n,$$

$$Y_j(t_k + 0) = |E_{jk} Y_j(t_k, \phi) - E_{jk} (y_j(t_k, \phi))|$$

$$\leq E_{jk} Y_j(t_k), \quad k \in \mathbb{Z}, \ j = 1, 2, \ldots, m.$$

Now define

$$U_i(t) = e^{\alpha t} X_i(t)^+, \quad i = 1, 2, \ldots, n,$$

$$V_j(t) = e^{\alpha t} Y_j(t)^+, \quad j = 1, 2, \ldots, m.$$ (17)

By using Young inequality $a^p b^q \leq \frac{a}{p} + \frac{b}{q}$, where $a, b, p, q > 0$ and $1/p + 1/q = 1$, it follows from (14)-(15) that

$$D^+ U_i(t)$$

$$\leq (\epsilon - ra_i^+) U_i(t)$$

$$+ re^\alpha \sum_{j=1}^m c_{ij}^+ L_j^j \int_0^\infty \mathcal{R}(s) ((X_i(t))^r)^{\frac{1}{r}} \, ds$$

$$+ re^\alpha \sum_{j=1}^m \sum_{q=1}^m (s_{ijq}^+ + s_{ijq}^-) M_q^i L_j^j \int_0^\infty \mathcal{R}(s) e^{\alpha V_j(t-s)} \, ds,$$

for $$t \geq 0, t \neq t_k, k \in \mathbb{Z}, i = 1, 2, \ldots, n.$$ Similarly, we have

$$D^+ V_j(t)$$

$$\leq (\epsilon - rb_j^+) V_j(t)$$

$$+ re^\alpha \sum_{i=1}^m d_{ij}^+ L_i^j \int_0^\infty \mathcal{R}(s) e^{\alpha U_i(t-s)} \, ds$$

$$+ re^\alpha \sum_{i=1}^m \sum_{p=1}^m (e_{ijp}^+ + e_{ijp}^-) M_p^j L_i^i \int_0^\infty \mathcal{R}(s) e^{\alpha U_i(t-s)} \, ds,$$

(19)

for $$t \geq 0, t \neq t_k, k \in \mathbb{Z}, j = 1, 2, \ldots, m.$$ Also,

$$U_i(t_k + 0) \leq H_{ik}^+ U_i(t_k), \quad k \in \mathbb{Z}, \ i = 1, 2, \ldots, n,$$

$$V_j(t_k + 0) \leq E_{jk}^+ V_j(t_k), \quad k \in \mathbb{Z}, \ j = 1, 2, \ldots, m.$$ (20)

Consider the candidate Lyapunov-Krasovskii functional as follows:

$$\forall(t) = \forall_1(t) + \forall_2(t),$$

(21)
where

\[ V_1(t) = \sum_{i=1}^{n} \lambda_i \left[ U_i(t) + \sum_{j=1}^{m} c_{ij}^L L_j^f \right] \times \int_{0}^{\infty} R(s) e^{\epsilon s} \left( \int_{t-\epsilon}^{t} V_j(z) dz \right) ds \]

\begin{align*}
&\quad + \sum_{j=1}^{m} \sum_{q=1}^{m} \left( s_{iqj}^+ + s_{qij}^+ \right) M_j^q L_j^f \\
&\quad \times \int_{0}^{\infty} R(s) e^{\epsilon s} \left( \int_{t-\epsilon}^{t} V_j(z) dz \right) ds \right] \right)
\end{align*}

\[ V_2(t) = \sum_{j=1}^{n} \lambda_{n+j} \left[ U_j(t) + \sum_{i=1}^{n} d_{ij}^L L_i^g \right] \times \int_{0}^{\infty} R(s) e^{\epsilon s} \left( \int_{t-\epsilon}^{t} U_i(z) dz \right) ds \]

\begin{align*}
&\quad + \sum_{i=1}^{n} \sum_{p=1}^{n} \left( e_{ip}^+ + e_{pji}^+ \right) M_i^p L_i^g \\
&\quad \times \int_{0}^{\infty} R(s) e^{\epsilon s} \left( \int_{t-\epsilon}^{t} U_i(z) dz \right) ds \right] \right)
\end{align*}

When \( t \neq t_k, k \in Z \), calculating the upper right Dini derivative of \( V_i(t) \) along the solutions of system (1), we get

\[ D^+ V_1(t) \]

\[ = \sum_{i=1}^{n} \lambda_i \left[ D^+ U_i(t) \right] \]

\begin{align*}
&\quad + \sum_{j=1}^{m} c_{ij}^L L_j^f \int_{0}^{\infty} R(s) e^{\epsilon s} \left( V_j(t) - V_j(t-s) \right) ds \\
&\quad + \sum_{j=1}^{m} \sum_{q=1}^{m} \left( s_{iqj}^+ + s_{qij}^+ \right) M_j^q L_j^f \\
&\quad \times \int_{0}^{\infty} R(s) e^{\epsilon s} \left( V_j(t) - V_j(t-s) \right) ds \right] \right)
\end{align*}

\[ \leq \sum_{i=1}^{n} \lambda_i \left[ (\epsilon - r a_i^-) U_i(t) \right] \]

\begin{align*}
&\quad + \sum_{j=1}^{m} \sum_{q=1}^{m} \left( s_{iqj}^+ + s_{qij}^+ \right) M_j^q L_j^f \\
&\quad \times \int_{0}^{\infty} R(s) e^{\epsilon s} \left( V_j(t) - V_j(t-s) \right) ds \right] \right)
\end{align*}

Similarly, we have

\[ D^+ V_2(t) \]

\[ \leq \sum_{j=1}^{n} \lambda_{n+j} \left[ (\epsilon - r b_j^-) V_j(t) \right] \]

\begin{align*}
&\quad + \sum_{i=1}^{n} \sum_{p=1}^{n} \left( e_{ip}^+ + e_{pji}^+ \right) M_i^p L_i^g \\
&\quad \times \int_{0}^{\infty} R(s) e^{\epsilon s} \left( V_j(t) - V_j(t-s) \right) ds \right] \right)
\end{align*}

Therefore, by Lemma 4, we obtain that

\[ D^+ V(t) \leq D^+ V_1(t) + D^+ V_2(t) \]

\[ \leq - \sum_{j=1}^{n} \lambda_j \left[ \epsilon g_j^- \right] U_j(t) \]

\[ \leq 0. \]
Now, we claim that
\[
\sum_{j=1}^{n} \lambda_{n_j} \left[ V_j (t_k + 0) \right.
+ \sum_{i=1}^{n} \sum_{p=1}^{m} \left( e_{jip}^r + e_{jip}^r \right) M_{ip}^B \right] \int_{t_k}^{t_{k+1}} U_i (z) dz ds
+ \sum_{i=1}^{n} \sum_{p=1}^{m} \left( s_{ijq}^r + s_{ijq}^r \right) M_{iq}^B \right] \int_{t_k}^{t_{k+1}} U_i (z) dz ds
\]
\[
\times \int_{0}^{\infty} \mathcal{R} (s) e^{s^r} \left( \int_{t_k}^{t_{k+1}} U_i (z) dz \right) ds
\]
\[
\leq \sum_{i=1}^{n} \sum_{j=1}^{n} \left[ \eta_i^k V_j (t_k + 0) \right.
+ \sum_{i=1}^{n} \sum_{p=1}^{m} \left( e_{jip}^r + e_{jip}^r \right) M_{ip}^B \right] \int_{t_k}^{t_{k+1}} U_i (z) dz ds
+ \sum_{i=1}^{n} \sum_{p=1}^{m} \left( s_{ijq}^r + s_{ijq}^r \right) M_{iq}^B \right] \int_{t_k}^{t_{k+1}} U_i (z) dz ds
\]
\[
\times \int_{0}^{\infty} \mathcal{R} (s) e^{s^r} \left( \int_{t_k}^{t_{k+1}} U_i (z) dz \right) ds
\]
\[
\leq \eta_i^k \mathcal{V} (t_k + 0).
\]

Then, for \( t \in (t_m, t_{m+1}] \), from (25), we have
\[
\mathcal{V} (t_{m+1}) \leq \mathcal{V} (t_m + 0).
\] (32)

On the other hand, from (26), we have
\[
\mathcal{V} (t_{m+1} + 0) \leq \eta_i^m \mathcal{V} (t_{m+1}).
\] (33)

From (31)–(33), we obtain
\[
\mathcal{V} (t_{m+1} + 0) \leq \eta_i^m \mathcal{V} (t_{m+1} + 0).
\] (34)

This shows that (27) holds for \( k = m + 1 \). Hence, by mathematical induction, (27) holds for all \( k \in \mathbb{Z} \). Combining (25) and (27), we obtain
\[
\mathcal{V} (t) \leq \mathcal{V} (t_k + 0) \leq \eta_i^k \eta_i^{k-1} \cdots \eta_i^1 \mathcal{V} (t_0),
\] (35)

for all \( t \in (t_k, t_{k+1}] \), \( k \in \mathbb{Z} \). Noticing that \( \eta_i^k \leq e^{\theta (t_k - t_{k-1})} \), \( k \in \mathbb{Z} \) in \( (S_k) \), we have
\[
\mathcal{V} (t) \leq \mathcal{V} (t_0) e^{\theta (t_k - t_{k-1})} e^{\theta (t_{k-1} - t_{k-2})} \cdots e^{\theta (t_1 - t_0)} \leq \mathcal{V} (0) e^{\theta t},
\] (36)

for all \( t \in (t_k, t_{k+1}] \), \( k \in \mathbb{Z} \). On the other hand, it follows from (21) that
\[
\mathcal{V} (t) \geq \lambda \left[ \sum_{i=1}^{n} U_i (t) + \sum_{j=1}^{m} V_j (t) \right] \geq \lambda \left[ \sum_{i=1}^{n} x_i (t, \phi) - x_i (t, \phi) \right] + \sum_{j=1}^{m} y_j (t, \phi) - y_j (t, \phi) \right] e^{\theta t},
\] (37)

for all \( t \in (t_k, t_{k+1}] \), \( k \in \mathbb{Z} \).
Together with (36)-(37), we have
\[
\sum_{i=1}^{n} |x_i (t, \phi) - x_i (t, \varphi)|^r + \sum_{j=1}^{m} |y_j (t, \phi) - y_j (t, \varphi)|^r
\leq \frac{\lambda^+}{\lambda^\Delta} \Delta e^{-(\varepsilon - \theta)t} \|\phi - \varphi\|_\Delta^r.
\]
for all \( t \geq 0 \). Let \( \mathcal{M} = ((\lambda^+/\lambda^\Delta))^{1/r} \), \( \alpha = (\varepsilon - \theta)/r \) and then we have
\[
\|z(t, \phi) - z(t, \varphi)\|_r \leq \mathcal{M} e^{-\alpha t} \|\phi - \varphi\|_\Delta.
\]
This completes the proof. \( \Box \)

In the following, we will study the existence, uniqueness, and global exponential stability of periodic solution of system (1) by exploiting Lemmas 5 and 6.

**Theorem 7.** Assume that assumptions (S1)–(S6) hold, then system (1) has a unique \( \omega \)-periodic solution, which is globally exponentially stable.

**Proof.** Firstly, we prove the existence of periodic solution of system (1). To this end, let \( z(t, \phi) = (x_1(t, \phi), x_2(t, \phi), \ldots, x_n(t, \phi), y_1(t, \phi), \ldots, y_m(t, \phi))^T \) be an arbitrary solution of system (1) through \((0, \phi)\), where \( \phi \in C^\omega \). Define \( z(t, \phi) = z(t + \omega, \phi) \), where \( \phi = z(s + \omega, \varphi), s \leq 0 \). We can know that \( \phi \in C^\omega \) and \( z(t, \phi) = (x_1(t, \phi), x_2(t, \phi), \ldots, x_n(t, \phi), y_1(t, \phi), y_2(t, \phi), \ldots, y_m(t, \phi))^T \) is also a solution of system (1) through \((0, \phi)\). By virtue of Lemma 6, we have
\[
\left\{ \sum_{i=1}^{n} |x_i (t, \phi) - x_i (t, \varphi)|^r + \sum_{j=1}^{m} |y_j (t, \phi) - y_j (t, \varphi)|^r \right\}^{1/r}
\leq \mathcal{M} e^{-\alpha t} \|\phi - \varphi\|_\Delta^r,
\]
for \( t \geq 0 \). So, we have
\[
\left\{ \sum_{i=1}^{n} |x_i (t + \omega, \phi) - x_i (t, \phi)|^r + \sum_{j=1}^{m} |y_j (t + \omega, \phi) - y_j (t, \phi)|^r \right\}^{1/r}
\leq \mathcal{M} e^{-\alpha t} \|\phi - \varphi\|_\Delta^r,
\]
for \( t \geq 0 \). It follows from Lemma 5 that
\[
\sum_{i=1}^{n} |x_i (t + \omega, \phi) - x_i (t, \phi)| + \sum_{j=1}^{m} |y_j (t + \omega, \phi) - y_j (t, \phi)|
\leq (n + m)^{1-1/r} \mathcal{M} e^{-\alpha t} \|\phi - \varphi\|_\Delta.
\]
Noticing that for \( i = 1, 2, \ldots, n \),
\[
x_i(t + k\omega, \varphi) = x_i(t, \varphi) + \sum_{s=1}^{k} \left[ x_i(t + s\omega, \varphi) - x_i(t + (s-1)\omega, \varphi) \right].
\] (44)

It follows from (43)-(44) that
\[
limit_{k \to \infty} x_i(t + k\omega, \varphi) = x_i(t, \varphi) + \sum_{s=1}^{k} \left[ x_i(t + s\omega, \varphi) - x_i(t + (s-1)\omega, \varphi) \right] \leq x_i(t, \varphi) + (n + m)^{(1-1/r)} \mathcal{M} \| \phi - \varphi \|_{\Delta} \lim_{k \to \infty} \sum_{s=1}^{k} e^{-\alpha(t+(s-1)\omega)}
\]
\[
\leq x_i(t, \varphi) + (n + m)^{(1-1/r)} \mathcal{M} e^{-\alpha t} \| \phi - \varphi \|_{\Delta} \sum_{s=1}^{\infty} e^{-\alpha(t-1)\omega}
\]
\[
< \infty,
\] (45)

which implies that \( \lim_{k \to \infty} x_i(t + k\omega, \varphi) \) exists. Similar to (44) and (45), we obtain that \( \lim_{k \to \infty} y_j(t + k\omega, \varphi) \) exists. Let
\[
z^*(t, \varphi^*) = \left( x_1^*(t, \varphi^*), x_2^*(t, \varphi^*), \ldots, x_n^*(t, \varphi^*) \right)^T,
\]
\[
y_1^*(t, \varphi^*), y_2^*(t, \varphi^*), \ldots, y_m^*(t, \varphi^*) \right)^T,
\] (46)

where \( \lim_{k \to \infty} x_i(t + k\omega, \varphi) = x_i^*(t, \varphi^*) \), \( \lim_{k \to \infty} y_j(t + k\omega, \varphi) = y_j^*(t, \varphi^*) \) for \( i = 1, 2, \ldots, n, j = 1, 2, \ldots, m \). Then \( z^*(t, \varphi^*) \) is an \( \omega \)-periodic solution for system (1).

Secondly, we prove the uniqueness of the periodic solution of system (1). Assume that \( z(t, \zeta) = (x_1(t, \zeta), x_2(t, \zeta), \ldots, x_n(t, \zeta), y_1(t, \zeta), y_2(t, \zeta), \ldots, y_m(t, \zeta)) \) is another \( \omega \)-periodic solution of system (1) through \((0, \zeta)\), where \( \zeta \in C^* \). By a minor modification of the proof of (43), we have
\[
\sum_{i=1}^{n} |x_i^*(t, \varphi^*) - x_i(t, \zeta)| + \sum_{j=1}^{m} |y_j^*(t, \varphi^*) - y_j(t, \zeta)|
\]
\[
= \left( \sum_{i=1}^{n} |x_i(t + k\omega, \varphi^*) - x_i(t, \zeta)| + \sum_{j=1}^{m} |y_j(t + k\omega, \varphi^*) - y_j(t, \zeta)| \right) \leq (n + m)^{(1-1/r)} \mathcal{M} e^{-\alpha t} \| \varphi - \zeta \|_{\Delta}, \quad t \geq 0.
\] (47)

Taking \( k \to \infty \), we have
\[
x_i^*(t, \varphi^*) = x_i(t, \zeta), \quad t \geq 0, i = 1, 2, \ldots, n,
\]
\[
y_j^*(t, \varphi^*) = y_j(t, \zeta), \quad t \geq 0, j = 1, 2, \ldots, m,
\] (48)

which implies that system (1) has a unique \( \omega \)-periodic solution.

Finally, since \( z^*(t, \varphi^*) \) is a unique \( \omega \)-periodic solution of system (1), let \( z(t, \psi) \) be any other solution of system (1) through \((0, \psi)\). From Lemma 6, we obtained that
\[
\|z(t, \psi) - z^*(t, \varphi^*)\|_{\Delta} \leq \mathcal{M} e^{-\alpha t} \| \psi - \varphi^* \|_{\Delta}, \quad t \geq 0,
\] (49)

where \( \psi, \varphi^* \in C^* \) and \( \alpha, \mathcal{M} \) are the same as defined in Lemma 6. It follows from Definition 2 that the \( \omega \)-periodic solution \( z^*(t, \varphi^*) \) is globally exponentially stable. Up to now, we conclude that system (1) has a unique \( \omega \)-periodic solution \( z^*(t, \varphi^*) \), which is globally exponentially stable. This completes the proof. \( \square \)

Remark 8. In assumption (S2), we only assume that the impulsive operators \( H_{jk}(-) \) and \( E_{jk}(-) \) are Lipschitz continuous, which remove the usual assumptions that the boundedness and linearity of the impulsive operators are required in [18, 19, 21, 29–31]. Thus, our results have wider adaptive range. Particularly, if we take the linear operators \( \Delta x_i(t_k) = -\gamma_{jk} x_i(t_k) \) and \( \Delta y_j(t_k) = -\alpha_{jk} y_j(t_k) \) as considered in [18, 19, 21, 29–31], that is,
\[
\begin{cases}
H_{jk}(x_i(t_k)) = (1-\gamma_{jk}) x_i(t_k), & \gamma_{jk} \in (0, 2), i = 1, 2, \ldots, n, j = 1, 2, \ldots, m,
E_{jk}(y_j(t_k)) = (1-\alpha_{jk}) y_j(t_k), & \alpha_{jk} \in (0, 2), j = 1, 2, \ldots, m, k = 1, 2, \ldots,
\end{cases}
\]

then we have \( H_{jk} = |1-\gamma_{jk}| < 1, E_{jk} = |1-\alpha_{jk}| < 1 \). So we can choose \( \eta_{jk} = 1 \) and \( \delta = 0 \) to satisfy assumption (S6). In this case, we have the following interesting corollary.

Corollary 9. Assume that assumptions ((S1)–(S6)) and (S7) hold; then system (1) has a unique \( \omega \)-periodic solution, which is globally exponentially stable.

Remark 10. Note that when \( t_k - t_{k-1} = \infty, k = 1, 2, \ldots \) in assumption (S9), which implies that there are no impulsive effects on system (1). Correspondingly, we call system (1) an impulse-free. In this case, we have the following corollary.

Corollary 11. Assume that assumptions ((S1)–(S6)) hold; then the impulse-free system (1) has a unique \( \omega \)-periodic solution, which is globally exponentially stable.

Remark 12. Clearly, based on the general \( \| \cdot \|_{\Delta} \), and Lemma 5, a general criterion ensuring the existence of periodic solution and its global exponential stability of system (1) with and without impulses has been established. Compared with results in [6, 7, 15–17], it is easy to see that our results are extended and improved because their results can be viewed as the special case of \( \eta = 1 \) in assumption (S6). In addition, since the nonnetwork parameter \( r \) is introduced in the condition (S6), it can allow much broader applications for designing the circuit of a convergent impulsive network.

Remark 13. In assumption (S3), if the kernel is a delta function of the form:
\[
K_{ij}(s) = R_{ij}(s) = \delta(s-r),
\]
\[
\overline{K}_{ij}(s) = \overline{R}_{ij}(s) = \delta(s-\sigma),
\] (50)
where \( \tau \geq 0 \) and \( \sigma \geq 0 \), then system (I) with continuously distributed delays reduces to the model with discrete delays in [29]. According to Lemma 3, we know that the condition (H3) of Theorem 3.1 in [29] implies that \( \Omega \) with \( r = 1 \) is an M-matrix but not vice versa. Thus, our results are new and complementary to their results.

4. An Example

In this section, an example and its numerical simulation are given to illustrate the correctness of the obtained theoretical results.

An Example. Consider the following high-order BAM neural networks with infinite distributed delays and impulses:

\[
\begin{align*}
\frac{dx_1(t)}{dt} &= -(8 + \sin 2t) x_1(t) \\
&
+ (2 + \cos 2t) \int_0^\infty e^{-s} f_1(y_1(t-s)) \, ds \\
&
+ 2 \sin 2t \int_0^\infty e^{-s} f_1(y_1(t-s)) f_1(y_1(t-s)) \, ds \\
&
+ \cos 2t, \quad t \neq t_k, \\
\end{align*}
\]

\[
\begin{align*}
x_1(t_k) &= x_1(t_k) + \Delta x_1(t_k) = H_{ik}(x_1(t_k)), \quad k = 1, 2, \ldots,
\end{align*}
\]

\[
\begin{align*}
\frac{dy_1(t)}{dt} &= -(10 - 3 \cos 2t) y_1(t) \\
&
+ (1 + \sin 2t) \int_0^\infty e^{-s} g_1(x_1(t-s)) \, ds \\
&
+ 2 \cos 2t \int_0^\infty e^{-s} g_1(x_1(t-s)) g_1(x_1(t-s)) \, ds \\
&
+ \sin 2t, \quad t \neq t_k, \\
\end{align*}
\]

\[
\begin{align*}
y_1(t_k) &= y_1(t_k) + \Delta y_1(t_k) = E_{ik}(y_1(t_k)), \quad k = 1, 2, \ldots,
\end{align*}
\]

(51)

where \( f_i(u) = g_i(u) = \text{tanh}(u) \). By simple calculation, we obtain that \( L^F_1 = L^I_1 = M^I_1 = M^P_1 = 1 \) and

\[
\Sigma = \begin{pmatrix}
7 & -7 \\
-6 & 6 + r
\end{pmatrix}.
\]

If the integer \( r \geq 1 \), then \( \Sigma \) is an M-matrix. Thus, assumptions \((S_1)-(S_4))\) are satisfied for system (51). For the impulsive part, the following two cases are considered.

Case 1. When \( t_k - t_{k-1} = \infty, \quad k = 1, 2, \ldots \), by Corollary II, we conclude that the impulse-free system (51) has a unique \( \pi \)-periodic solution, which is globally exponentially stable.

Case 2. When the impulsive parts are taken as the nonlinear operators such that \( \Delta x_i(t_k) = \gamma \tan(x_i(t_k)), \gamma \in (0, 2) \) and \( \Delta y_i(t_k) = \gamma \tan(y_i(t_k)), \gamma \in (0, 2) \), that is,

\[
\begin{align*}
H_{ik}(x_1(t_k)) &= x_1(t_k) - \gamma \tan(x_1(t_k)), \quad \gamma \in (0, 2), \quad k = 1, 2, \ldots,
\end{align*}
\]

\[
\begin{align*}
E_{ik}(y_1(t_k)) &= y_1(t_k) - \gamma \tan(y_1(t_k)), \quad \gamma \in (0, 2), \quad k = 1, 2, \ldots,
\end{align*}
\]

(53)

which satisfy the assumption \((S_2)\) with Lipschitz constants \( H_{ik} = E_{ik} \leq |1 - y| < 1, \quad k = 1, 2, \ldots \). So we can choose \( \eta_k = 1 \) and \( \theta = 0 \) to satisfy the assumption \((S_3)\). According to Theorem 7, we conclude that the impulsive system (51) has a unique \( \pi \)-periodic solution, which is globally exponentially stable. However, in this case, results in [18, 19, 21, 29–31] are ineffective because the function \( \tan(\cdot) \) is nonlinear. Moreover, the condition \((H_3)\) of Theorem 3.1 in [29] cannot be applied to system (51), since \( b^*_1 - c^*_i L^I_1 - 2s^*_i M^I_1 L^I_1 = 0 \neq 0 \).

5. Conclusions

In this paper, we have studied the existence, uniqueness, and global exponential stability of periodic solution for a kind of high-order BAM neural networks with continuously distributed delays and general impulses. It should be noted that some extended and improved criteria have been derived by exploiting the general \( \| \cdot \|_\rho \), Lemma 5, and the Lyapunov functional method. In addition, these criteria are in terms of \( M \)-matrix, which can be easily checked by many equivalent conditions listed in [32]. Finally, an example and its numerical simulation are given to show the feasibility and correctness of the obtained results.
