THEOREMS OF URQUHART AND STEINER-LEHMUS IN THE POINCARÉ BALL MODEL OF HYPERBOLIC GEOMETRY

Oğuzhan Demirel and Emine Soytürk Seyranrete

Abstract. In [Comput. Math. Appl. 41 (2001), 135–147], A.A. Ungar employs the Möbius gyrovector spaces for the introduction of the hyperbolic trigonometry. This A.A. Ungar’s work, plays a major role in translating some theorems in Euclidean geometry to corresponding theorems in hyperbolic geometry. In this paper we present (i) the hyperbolic Breusch’s lemma, (ii) the hyperbolic Urquhart’s theorem, and (iii) the hyperbolic Steiner-Lehmus theorem in the Poincaré ball model of hyperbolic geometry by employing results from A.A. Ungar’s work.

1. Introduction

This paper is inspired by the beautiful papers [9, 15] by A.A. Ungar on hyperbolic trigonometry. A.A. Ungar showed that the hyperbolic sine and the hyperbolic cosine rules are valid in the Poincaré ball model of hyperbolic geometry in a form analogous to their Euclidean counterparts. In this paper we shall apply hyperbolic trigonometry to the study of the hyperbolic Breusch’s Lemma, the hyperbolic Urquhart’s theorem and the hyperbolic Steiner-Lehmus theorem in the Poincaré ball model of hyperbolic geometry. In the Poincaré ball model, a gyroline (or, a hyperbolic line) is an Euclidean semicircular arc that intersects the boundary of the ball orthogonally.

2. Möbius transformations of the disc

In complex analysis Möbius transformations are well known and fundamental. The most general Möbius transformation of the complex open unit disc $\mathbb{D} = \{z \in \mathbb{C} : |z| < 1\}$ in the complex $z$-plane

$$z \mapsto e^{it} \frac{z_0 + z}{1 + \overline{z_0}z} = e^{it} (z_0 \oplus z)$$

2010 AMS Subject Classification: 51B10, 51M10, 30F45, 20N05.

Keywords and phrases: Möbius transformation; Gyrogroups; Hyperbolic geometry; Gyrovector spaces and hyperbolic trigonometry.
defines the Möbius addition $\oplus$ in the disc, allowing the Möbius transformation of the disc to be viewed as a Möbius left gyrotranslation

$$
 z \mapsto z_0 \oplus z = \frac{z_0 + z}{1 + \overline{z_0} z}
$$

followed by a rotation. Here $\theta$ is a real number, $z_0 \in \mathbb{D}$, and $\overline{z_0}$ is the complex conjugate of $z_0$. Möbius subtraction $\ominus$ is given by $a \ominus z = a \oplus (-z)$, clearly $z \ominus z = 0$ and $\ominus z = -z$. Möbius addition $\oplus$ is a binary operation in the disc $\mathbb{D}$, but clearly it is neither commutative nor associative. Möbius addition $\oplus$ gives rise to the groupoid $(\mathbb{D}, \oplus)$ studied by A.A. Ungar in several books including [8, 10, 13, 15, 16]. Möbius addition is analogous to the common vector addition $+$ in Euclidean plane geometry. Since Möbius addition $\oplus$ is not associative, the groupoid $(\mathbb{D}, \oplus)$ is not a group. However, it has a group-like structure that we present below.

The breakdown of commutativity in Möbius addition is “repaired” by the introduction of gyrator,

$$
gyr : \mathbb{D} \times \mathbb{D} \rightarrow Aut(\mathbb{D}, \oplus)
$$

which gives rise to gyrations,

$$
gyr [a, b] = \frac{a \oplus b}{b \oplus a} = \frac{1 + \overline{ab}}{1 + \overline{a}b}
$$

where $Aut(\mathbb{D}, \oplus)$ is the automorphism group of the groupoid $(\mathbb{D}, \oplus)$. Therefore, the gyrocommutative law of Möbius addition $\oplus$ follows from the definition of gyration in (1),

$$
a \oplus b = gyr [a, b] (b \ominus a).
$$

Coincidentally, the gyration $gyr[a, b]$ that repairs the breakdown of the commutative law of $\oplus$ in (2), repairs the breakdown of the associative law of $\oplus$ as well, giving rise to the respective left and right gyroassociative laws

$$
a \oplus (b \oplus c) = (a \oplus b) \oplus gyr [a, b] c
$$

$$
(a \oplus b) \ominus c = a \ominus (b \oplus gyr [b, a] c)
$$

for all $a, b, c \in \mathbb{D}$.

**Definition 1.** A groupoid $(\mathbb{G}, \oplus)$ is a gyrogroup if its binary operation satisfies the following axioms

\begin{align*}
(G1) & \quad 0 \oplus a = 0 \\
(G2) & \quad \ominus a \oplus a = 0 \\
(G3) & \quad a \oplus (b \oplus c) = (a \oplus b) \oplus gyr [a, b] c \\
(G4) & \quad gyr [a, b] \in Aut(\mathbb{G}, \oplus) \\
(G5) & \quad gyr [a, b] = gyr [a \oplus b, b]
\end{align*}

for all $a, b, c \in \mathbb{G}$. 
Additionally, if the binary operation “⊕” obeys the gyrocommutative law

\[(G6) \quad a \oplus b = gyr [a, b] (b \oplus a) \quad \text{gyrocommutative Law}\]

for all \(a, b, c \in G\), then \((G, \oplus)\) is called a gyrocommutative gyrogroup. It is easy to see that \(-a = \ominus a\) for all elements \(a\) of \(G\).

Clearly, with these properties, one can now readily check that the Möbius complex disc groupoid \((\mathbb{D}, \oplus)\) is a gyrocommutative gyrogroup.

The axioms in Definition 1 imply the right identity property, the right inverse property, the right gyroassociative law and the right loop property. We refer readers to [8, 10, 13, 15, 16] for more details about gyrogroups.

3. Möbius gyrogroups: From disc to the ball

Let us identify complex numbers of the complex plane \(\mathbb{C}\) with vectors of the Euclidean plane \(\mathbb{R}^2\) in the usual way:

\[\mathbb{C} \ni u = u_1 + iu_2 = (u_1, u_2) = u \in \mathbb{R}^2.\]

Then the equations

\[u \cdot v = \text{Re}(\overline{u}v), \quad \|u\| = |u|. \quad (3)\]

give the inner product and the norm in \(\mathbb{R}^2\), so that Möbius addition in the disc \(\mathbb{D}\) of \(\mathbb{C}\) becomes Möbius addition in the disc \(\mathbb{R}^2 = \{v \in \mathbb{R}^2 : \|v\| < 1\}\) of \(\mathbb{R}^2\). Indeed, we get from (3) that

\[u \oplus v = \frac{u + v}{1 + \overline{u}v} = \frac{(1 + u\overline{v})(u + v)}{(1 + \overline{u}v)(1 + u\overline{v})} = \frac{(1 + \overline{u}v + \overline{u}v + |v|^2)u + (1 - |u|^2)v}{1 + \overline{u}v + \overline{u}v + |u|^2|v|^2} = \frac{(1 + 2u \cdot v + \|v\|^2)u + (1 - \|u\|^2)v}{1 + 2u \cdot v + \|u\|^2|v|^2} = u \oplus v \quad (4)\]

for all \(u, v \in \mathbb{D}\) and all \(u, v \in \mathbb{R}^2\).

4. Möbius addition in the ball

Let \(\mathbb{V}\) be any real inner-product space and

\[\mathbb{V}_s = \{v \in \mathbb{V} : \|v\| < s\}\]

be the open ball of \(\mathbb{V}\) with radius \(s > 0\). Möbius addition in \(\mathbb{V}_s\) is motivated by (4). It is given by the equation

\[u \oplus v = \frac{(1 + (2/s^2)u \cdot v + (1/s^2)\|v\|^2)u + (1 - (1/s^2)\|u\|^2)v}{1 + (2/s^2)u \cdot v + (1/s^2)\|u\|^2|v|^2} \quad (5)\]

where \(\cdot\) and \(\|\cdot\|\) are the inner product and norm that the ball \(\mathbb{V}_s\) inherits from its space \(\mathbb{V}\) and where, ambiguously, + denotes both addition of real numbers on the real line and addition of vectors in \(\mathbb{V}\).
Without loss of generality, we may assume that \( s = 1 \) in (5). However we prefer to keep \( s \) as a free positive parameter in order to exhibit the results that in the limit as \( s \to \infty \), when the ball \( V_s \) expands to the whole of its real inner product space \( V \), and Möbius addition \( \oplus \) reduces to vector addition \( + \) in \( V \), i.e.,

\[
\lim_{s \to \infty} u \oplus v = u + v \quad \text{and} \quad \lim_{s \to \infty} V_s = V.
\]

Möbius scalar multiplication is given by the equation

\[
r \odot v = s \frac{(1 + \|v\|/s)}{1 + \|v\|/s} - \frac{(1 - \|v\|/s)}{1 + \|v\|/s} v
\]

\[
= s \tanh \left( \frac{r \tanh^{-1} \|v\|/s}{\|v\|} \right) \frac{v}{\|v\|}
\]

where \( r \in \mathbb{R}, u, v \in V, v \neq 0 \) and \( r \odot 0 = 0 \).

Möbius scalar multiplication possesses the following properties:

\[
\begin{align*}
a \odot v &= v \odot v \odot \cdots \odot v \quad \text{\( n \)-terms} \\
(r_1 + r_2) \odot v &= r_1 \odot v \odot r_2 \odot v \quad \text{scalar distribute law} \\
(r_1 r_2) \odot v &= r_1 \odot (r_2 \odot v) \quad \text{scalar associative law} \\
r \odot (r_1 \odot v \odot r_2 \odot v) &= r \odot (r_1 \odot v) \odot r \odot (r_2 \odot v) \quad \text{monodistributive law} \\
\|r \odot v\| &= |r| \odot \|v\| \quad \text{homogeneity property} \\
\|r \odot v\| &= \frac{v}{\|v\|} \quad \text{scaling property} \\
gyr[a, b](r \odot v) &= r \odot gyr[a, b] \odot v \quad \text{gyroautomorphism property} \\
1 \odot v &= v \quad \text{multiplicative unit property}
\end{align*}
\]

**Definition 2 (Möbius gyrovector spaces).** Let \((V_s, \oplus)\) be a Möbius gyrogroup equipped with scalar multiplication \( \odot \). The triple \((V_s, \oplus, \odot)\) is called a Möbius gyrovector space.

5. **Möbius geodesics and angles**

As it is well known from Euclidean geometry, the straight line passing through two given points \( A \) and \( B \) of vector space \( \mathbb{R}^n \) can be represented by the expression

\[
A + (-A + B) t
\]

\( t \in \mathbb{R} \). Obviously it passes through \( A \) when \( t = 0 \), and through \( B \) when \( t = 1 \).

In full analogy with Euclidean geometry, the unique Möbius geodesic passing through two given points \( A \) and \( B \) of a Möbius gyrovector space \((V_s, \oplus, \odot)\) is represented by the parametric gyrovector equation

\[
L_{AB} = A \oplus (\odot A \oplus B) \odot t
\]

with parameter \( t \in \mathbb{R} \). It passes through \( A \) when \( t = 0 \), and through \( B \) when \( t = 1 \). The gyroline \( L_{AB} \) turns out to be a circular arc that intersects the boundary of the
The theorems of Urquhart and Steiner-Lehmus

ball $V_s$ orthogonally. The gyromidpoint $M_{AB}$ of the points $A$ and $B$ corresponds to the parameter $t = 1/2$ of the gyroline $L_{AB}$, see [11],

$$M_{AB} = A \oplus (\ominus A \oplus B) \odot \frac{1}{2}.$$  

The measure of a Möbius angle between two intersecting geodesic rays equals the measure of the Euclidean angle between corresponding intersecting tangent lines, as shown in Fig. 1.

![Fig 1. The unique 2-dimensional geodesics that passes through two given points and the hyperbolic angle between two intersecting geodesics rays in a Möbius gyrovector plane ($\mathbb{R}^2_s; \oplus, \odot$). For the non-zero gyrovectors $\ominus A \oplus B$ and $\ominus A \oplus C$ or equivalently $\ominus A \oplus E$ and $\ominus A \oplus D$ the measure of the gyroangle $\alpha$ given by the equation $\cos \alpha = \frac{\ominus A \oplus B}{\|\ominus A \oplus B\|} \cdot \frac{\ominus A \oplus C}{\|\ominus A \oplus C\|}$ or equivalently by the equation $\cos \alpha = \frac{\ominus A \oplus E}{\|\ominus A \oplus E\|} \cdot \frac{\ominus A \oplus D}{\|\ominus A \oplus D\|}$. The hyperbolic angle is invariant under left gyrotranslations and rotations, see [7].

DEFINITION 3. The hyperbolic distance function in $\mathbb{R}^n_s$, given by the equation

$$d(A, B) = \|A \odot B\|.$$  

for $A, B \in \mathbb{R}^n_s$.

6. Gyrotriangles and gyrotrigonometry in Möbius gyrovector space

DEFINITION 4. A gyrotriangle $\triangle ABC$ in a gyrovector space $(V_s, \oplus, \odot)$ is a gyrovector space object formed by the three points $A, B, C \in V_s$, called the vertices of the gyrotriangle, and the gyrovectors $\ominus A \oplus B$, $\ominus B \oplus C$ and $\ominus C \oplus A$, called the sides of the gyrotriangle. These are respectively the sides opposite to the vertices $C, A$ and $B$. The gyrotriangle sides generate the three gyrotriangle gyroangles $\alpha, \beta$ and $\gamma$ at the respective vertices $A, B$ and $C$, as shown in Fig. 2 below.

THEOREM 5. [10] Let $\triangle ABC$ be a gyrotriangle in a Möbius gyrovector space $(V_s, \oplus, \odot)$ with vertices $A, B$ and $C$, corresponding gyroangles $\alpha, \beta, \gamma$, $0 < \alpha + \beta + \gamma < \frac{\pi}{2}$.
\[ \beta + \gamma < \pi, \text{ and side gyrolengths } \| \oplus B \oplus C \|, \| \oplus C \oplus A \|, \| \oplus A \oplus B \|. \text{ The side}
\]
gyrolengths of the gyrotriangle \( \Delta ABC \) are determined by its gyroangles according to the AAA to SSS conversion equations

\[
\left( \frac{\| \oplus B \oplus C \|}{s} \right)^2 = \frac{\cos \alpha + \cos (\beta + \gamma)}{\cos \alpha + \cos (\beta - \gamma)}
\]
\[
\left( \frac{\| \oplus C \oplus A \|}{s} \right)^2 = \frac{\cos \beta + \cos (\alpha + \gamma)}{\cos \beta + \cos (\alpha - \gamma)}
\]
\[
\left( \frac{\| \oplus A \oplus B \|}{s} \right)^2 = \frac{\cos \gamma + \cos (\alpha + \beta)}{\cos \gamma + \cos (\alpha - \beta)}
\]

The hyperbolic law of cosine and the hyperbolic law of sine can be recast in a form fully analogous to the form of their Euclidean counterparts. Let us use the notation \( \| a \|_M = \gamma_a \| a \| \) where \( \gamma_a \) is the gamma factor

\[
\gamma_a = \frac{1}{\sqrt{1 - \| a \|^2}},
\]
so that, conversely

\[
\frac{\| a \|}{s} = \frac{2 (\| a \|_M / s)}{1 + \sqrt{1 + 4 (\| a \|_M / s)^2}}.
\]

**Theorem 6.** [9] Let \( \Delta ABC \) be a gyrotriangle in a Möbius gyrovector space \((V_s, \oplus, \otimes)\) with vertices \( A, B, C \in V_s \) and sides \( a = \oplus B \oplus C \), \( b = \oplus C \oplus A \) and \( c = \oplus A \oplus B \) with hyperbolic angles \( \alpha, \beta \) and \( \gamma \) at the vertices \( A, B \) and \( C \). Then we have the hyperbolic law of sine,

\[
\frac{\| a \|_M}{\sin \alpha} = \frac{\| b \|_M}{\sin \beta} = \frac{\| c \|_M}{\sin \gamma}.
\]

**Theorem 7.** [9] Let \( \Delta ABC \) be a gyrotriangle in a Möbius gyrovector space \((V_s, \oplus, \otimes)\) with vertices \( A, B, C \in V_s \) and sides \( a = \oplus B \oplus C \), \( b = \oplus C \oplus A \) and
The theorems of Urquhart and Steiner-Lehmus

\[ c = \ominus A \oplus B \] with hyperbolic angles \( \alpha, \beta \) and \( \gamma \) at the vertices \( A, B \) and \( C \). Then we have the hyperbolic law of cosine,

\[
\frac{1}{s^2} = \frac{1}{a^2} + \frac{1}{b^2} \ominus \frac{1}{s} \left( 1 + \frac{a^2}{s^2} \right) \left( 1 + \frac{b^2}{s^2} \right) \frac{2ab \cos \gamma}{s} \cos \gamma .
\]

where \( a = \|a\|, b = \|b\|, c = \|c\| \).

Theorem 8. \([9]\) Let \( \Delta ABC \) be a gyrotriangle in a Möbius gyrovector space \((V_s, \oplus, \otimes)\) with vertices \( A, B, C \in V_s \) and sides \( a = \ominus B \oplus C, b = \ominus C \oplus A \) and \( c = \ominus A \oplus B \) with hyperbolic angles \( \alpha, \beta \) and \( \gamma \) at the vertices \( A, B \) and \( C \). If \( \gamma = \pi/2 \) then we have the hyperbolic Pythagorean identity,

\[
\frac{1}{s^2} = \frac{1}{a^2} + \frac{1}{b^2}
\]

where \( a = \|a\|, b = \|b\|, c = \|c\| \).

7. The theorems of Urquhart and Steiner-Lehmus in the Poincaré ball model of hyperbolic geometry

In literature, Urquhart’s theorem is also known as the most elementary theorem of Euclidean geometry since it involves only the concept of straight line and distance. Urquhart discovered this result when considering some of the fundamental concepts of the theory of special relativity. The origin and some history of this theorem, we refer \([5]\).

Many authors give the proof of this theorem in different ways. In \([18]\), an elementary synthetic proof of Urquhart’s theorem has been posted at Professor’s Wu online forum at Berkeley. In \([17]\), K.S. Williams and in \([3]\), M. Hajja gave the proofs which only involved the sine formula for triangles and a few simple trigonometric identities.

In \([15]\), A.A. Ungar proved the hyperbolic Breusch’s lemma, the hyperbolic Urquhart’s theorem and hyperbolic Steiner-Lehmus theorem in the Einstein gyrovector plane \((B^2_s, \oplus, \otimes)\), but there is no attempt made for obtaining these results in the Poincaré ball model of hyperbolic geometry. In this paper, we give affirmative answer of the problem explained above.

Theorem 9. (Breusch’s Lemma in Euclidean Geometry) Let \( \Delta ABC_k, k = 1, 2 \), be two triangles in Euclidean plane \( \mathbb{R}^2 \) with common side \( AB \), with sides \( a_k, b_k, c_k \), and with angles \( \alpha_k, \beta_k, \gamma_k \), as shown in Fig. 3. Then

\[ a_1 + b_1 = a_2 + b_2 \iff \tan \frac{\alpha_1}{2} \tan \frac{\beta_1}{2} = \tan \frac{\alpha_2}{2} \tan \frac{\beta_2}{2} . \]

For the proof, we refer to \([15]\) or \([6]\).

Theorem 10. (Urquhart’s Theorem in Euclidean geometry) Let \( \Delta AD_1 BD_2 \) be a concave quadrilateral in a Euclidean plane \( \mathbb{R}^2 \), and let \( AD_1 \) meet \( D_2 B \) at \( C_1 \), and \( AD_2 \) meet \( D_1 B \) at \( C_2 \), as shown in Fig. 4. Then

\[ |AC_1| + |C_1B| = |AC_2| + |C_2B| \iff |AD_1| + |D_1B| = |AD_2| + |D_2B| . \]
For the proof, we refer to [15] or [3].

Let us give a trigonometric example which plays a major role in the proofs of the hyperbolic Breusch’s lemma and hyperbolic Urquhart’s theorem in the Poincaré ball model of hyperbolic geometry.

**Example 11.** Let $\Delta ABC$ be a gyrotriangle in a Möbius gyrovector space $(\mathbb{R}_n^s, \oplus, \otimes)$ with vertices $A, B, C \in \mathbb{R}_n^s$ and sides $a = \ominus B \oplus C$, $b = \ominus C \oplus A$ and $c = \ominus A \oplus B$ with hyperbolic angles $\alpha, \beta$ and $\gamma$ at the vertices $A, B$ and $C$. Then

$$\frac{\sin \alpha + \sin \beta}{\sin (\alpha + \beta)} = \frac{1}{c_s} \frac{\gamma_a^2 a_s + \gamma_b^2 b_s}{\gamma_b^2 \gamma_c^2 (1 - a_s^2 b_s^2 c_s^2)}$$

where $a_s = ||a||/s$, $b_s = ||b||/s$, $c_s = ||c||/s$.

Indeed, from the well known gyrotrigonometric functional identity $\sin (\alpha + \beta) = \sin \alpha \cos \beta + \sin \beta \cos \alpha$, and applying the following identities to gyrotriangle $\Delta ABC$, see [10], we easily get to desired result:

$$\frac{b_s c_s}{\gamma_a^2} \sin \alpha = \frac{a_s c_s}{\gamma_b^2} \sin \beta = \frac{a_s b_s}{\gamma_c^2} \sin \gamma,$$

$$\cos \alpha = -\frac{a_s^2 + b_s^2 + c_s^2 - a_s^2 b_s^2 c_s^2}{2b_s c_s},$$

$$\cos \beta = \frac{a_s^2 - b_s^2 + c_s^2 - a_s^2 b_s^2 c_s^2}{2a_s c_s},$$

$$\cos \gamma = \frac{a_s^2 + b_s^2 - c_s^2 - a_s^2 b_s^2 c_s^2}{2a_s b_s}.$$

Let us give the hyperbolic Breusch’s lemma, and the hyperbolic Urquhart’s theorem in the Poincaré ball model of hyperbolic geometry.
Theorem 12. (Breusch’s Lemma in Hyperbolic geometry) Let $\triangle ABC_k$, $k = 1, 2$, be two gyrotriangles in a M"obius gyrovector space $(\mathbb{R}^n_\alpha, \oplus, \otimes)$ with common side $\odot A \oplus B$, with side gyrolenghts $a_k, b_k, c_k$, and with angles $\alpha_k, \beta_k, \gamma_k$, as similar to Fig. 3. Then

$$\frac{\gamma_2^2 a_1 + \gamma_1^2 b_1,}{\gamma_2^2 a_1, (1 - a_1^2 b_1^2)} = \frac{\gamma_2^2 a_2, + \gamma_1^2 b_2,}{\gamma_2^2 a_2, \gamma_2 b_2, (1 - a_2^2 b_2^2)} \iff \tan \frac{\alpha_1,}{2} \tan \frac{\beta_1,}{2} = \tan \frac{\alpha_2,}{2} \tan \frac{\beta_2,}{2}.$$

Proof. First of all, since any trigonometric identity is identical with a corresponding gyrotrigonometric identity, the following identity is valid in trigonometry when $\sin (\alpha + \gamma) \neq 0$, and hence in gyrotrigonometry as well:

$$\frac{\sin \alpha + \sin \gamma}{\sin (\alpha + \gamma)} = -1 + \frac{2}{1 - \frac{\alpha}{2} \tan \frac{\gamma}{2}}.$$

Therefore, we get

$$\frac{\gamma_2^2 a_1, + \gamma_1^2 b_1,}{\gamma_2^2 a_1, (1 - a_1^2 b_1^2)} = \frac{\gamma_2^2 a_2, + \gamma_1^2 b_2,}{\gamma_2^2 a_2, \gamma_2 b_2, (1 - a_2^2 b_2^2)} \iff \frac{\sin \alpha_1 + \sin \beta_1,}{\sin (\alpha_1 + \beta_1)} = \frac{\sin \alpha_2 + \sin \beta_2,}{\sin (\alpha_2 + \beta_2)}$$

$$\iff \tan \frac{\alpha_1,}{2} \tan \frac{\beta_1,}{2} = \tan \frac{\alpha_2,}{2} \tan \frac{\beta_2,}{2}.$$ 

Theorem 13. (Urquhart’s Theorem in Hyperbolic geometry) Let $\triangle AD_1BD_2$ be a concave gyroquadrilateral in a M"obius gyrovector space $(\mathbb{R}^n_\alpha, \oplus, \otimes)$ where $\alpha_k = \angle BAC_k$, $\beta_k = \angle ABC_k$, and $\gamma_k = \angle AC_kB$, and let $AD_1$ meet $D_2B$ at $C_1$, and $AD_2$ meet $D_1B$ at $C_2$, as shown in Fig. 5. Then

$$\frac{\gamma_2^2 a_1, + \gamma_1^2 b_1,}{\gamma_2^2 a_1, (1 - a_1^2 b_1^2)} = \frac{\gamma_2^2 a_2, + \gamma_2^2 b_2,}{\gamma_2^2 a_2, (1 - a_2^2 b_2^2)} \iff \frac{\gamma_2^2 a_1^\prime, + \gamma_1^2 b_1^\prime,}{\gamma_2^2 a_1^\prime, (1 - a_1^\prime b_1^\prime)} = \frac{\gamma_2^2 a_2^\prime, + \gamma_2^2 b_2^\prime,}{\gamma_2^2 a_2^\prime, (1 - a_2^\prime b_2^\prime)}$$

where $a_k = \|\odot C_k \oplus B\|$, $b_k = \|\odot C_k \oplus A\|$, $a_1^\prime = \|\odot D_k \oplus B\|$, $b_1^\prime = \|\odot D_k \oplus A\|$.

Fig. 5. A concave gyroquadrilateral $AD_1BD_2$ in a M"obius gyrovector space $(\mathbb{R}^n_\alpha, \oplus, \otimes)$ with $\alpha_k = \angle BAC_k$, $\beta_k = \angle ABC_k$, and $\gamma_k = \angle AC_kB$, satisfying $AD_1$ meet $D_2B$ at $C_1$, and $AD_2$ meet $D_1B$ at $C_2$. 
Proof. Applying the hyperbolic Breusch’s lemma to each of the two gyrotriangles $\Delta ABC_k$ and $\Delta AB D_k$, $k = 1, 2$, we have

$$\frac{\gamma_{a_1} a_1 + \gamma_{b_1} b_1}{\gamma_{a_1}^2 \gamma_{b_1} (1 - a_1^2 b_1^2)} = \frac{\gamma_{a_2} a_2 + \gamma_{b_2} b_2}{\gamma_{a_2}^2 \gamma_{b_2} (1 - a_2^2 b_2^2)} \implies \tan \frac{\alpha_1}{2} \tan \frac{\beta_1}{2} = \tan \frac{\alpha_2}{2} \tan \frac{\beta_2}{2}$$

and

$$\frac{\gamma_{a_1}^2 a_1 + \gamma_{b_1}^2 b_1}{\gamma_{a_1}^2 \gamma_{b_1}^2 (1 - a_1^2 b_1^2)} = \frac{\gamma_{a_2}^2 a_2 + \gamma_{b_2}^2 b_2}{\gamma_{a_2}^2 \gamma_{b_2}^2 (1 - a_2^2 b_2^2)} \implies \tan \frac{\alpha_1}{2} \tan \left( \pi - \frac{\beta_1}{2} \right) = \tan \frac{\alpha_2}{2} \tan \left( \pi - \frac{\beta_1}{2} \right)$$

(6)

respectively. Clearly, the right-hand side of (6) implies the equality

$$\tan \frac{\alpha_1}{2} \tan \frac{\beta_1}{2} = \tan \frac{\alpha_2}{2} \tan \frac{\beta_2}{2}$$

and so the proof is completed. $\blacksquare$

**Theorem 14.** (Steiner-Lehmus Theorem in Hyperbolic Geometry) Let $\Delta ABC$ be a gyrotriangle in a M"{o}bius gyrovector space $(\mathbb{R}_+^n, \circ, \odot)$ having two equal internal gyroangle bisectors (each measured from a vertex to the opposite side). Then the gyrotriangle $\Delta ABC$ is isosceles.

**Proof.** Given a gyrotriangle $\Delta ABC$, $\|B \oplus E\|$ and $\|C \oplus D\|$ are equal bisectors of the gyroangles $\angle ABC := 4\alpha$ and $\angle ACB := 4\beta$, respectively. Clearly, if we prove that the equality $\|B \oplus D\| = \|E \oplus C\|$ holds true, this implies the equality of the gyrolength $\|A \oplus B\|$ to the gyrolength $\|A \oplus C\|$. Without loss of generality, we may assume $\|B \oplus D\| \geq \|E \oplus C\|$. Now, to prove $\|B \oplus D\| = \|E \oplus C\|$, suppose the contrary that $\|B \oplus D\| > \|E \oplus C\|$. This implies $\|B \oplus D\|^2 > \|E \oplus C\|^2$ and applying the hyperbolic cosine law to the gyrotriangles $\Delta BDC$ and $\Delta EBC$ we get $\cos 2\alpha > \cos 2\beta$. Since $2\alpha, 2\beta \in I = (0, \pi/2)$ and cosine function is decreasing on $I$, we get $\beta > \alpha$. Since the tangent function is increasing on $I$, we get $\tan \beta > \tan \alpha$ and this implies

$$\frac{2}{1 - \tan \alpha \tan \beta} > \frac{2}{1 - \tan \alpha \tan \beta}.$$

Applying the hyperbolic Breusch’s lemma to the gyrotriangles $\Delta EBC$ and $\Delta DBC$, we have

$$\frac{\gamma_{E \oplus C}^2 \|E \oplus C\|^s + \gamma_{B \oplus E}^2 \|B \oplus E\|^s}{\gamma_{E \oplus C}^2 \gamma_{B \oplus E}^2 (1 - \|E \oplus C\|^2 \|B \oplus E\|^2)} > \frac{\gamma_{B \oplus D}^2 \|B \oplus D\|^s + \gamma_{D \oplus C}^2 \|D \oplus C\|^s}{\gamma_{B \oplus D}^2 \gamma_{D \oplus C}^2 (1 - \|B \oplus D\|^2 \|D \oplus C\|^2)}.$$
Now define a function $f$ from $[0, s)$ to $\mathbb{R}$ by the rule
\[
f(x) = \frac{xs}{s^2 - x^2} + \frac{ks}{s^2 - k^2} \frac{s^2 - k^2}{s^2 - x^2 - s^2 - k^2}
\]
where $k$ and $s$ are fixed elements of $\mathbb{R}$ such that $0 \leq k < s$. A simple calculation shows that $f$ is an increasing function and therefore from (7), we get $\|\otimes E \oplus C\| > \|\otimes B \oplus D\|$ which is the desired contradiction.

Finally, applying the hyperbolic cosine law to the gyrotriangles $\triangle DBC$ and $\triangle EBC$, we get $2\alpha = 2\beta$, i.e. $\|\otimes A \oplus B\| = \|\otimes A \oplus C\|$.
