LINEAR STRUCTURES ON LOCALES

PEDRO RESENDE AND JOÃO PAULO SANTOS

Abstract. We define a notion of morphism for quotient vector bundles that yields both a category $QVBun$ and a contravariant global sections functor $C : QVBun^{op} \to Vect$ whose restriction to trivial vector bundles with fiber $F$ coincides with the contravariant functor $Top^{op} \to Vect$ of $F$-valued continuous functions. Based on this we obtain a linear extension of the adjunction between the categories of topological spaces and locales: (i) a linearized topological space is a spectral vector bundle, by which is meant a mildly restricted type of quotient vector bundle; (ii) a linearized locale is a locale $\triangle$ equipped with both a topological vector space $A$ and a $\triangle$-valued support map for the elements of $A$ satisfying a continuity condition relative to the spectrum of $\triangle$ and the lower Vietoris topology on $\text{Sub} \ A$; (iii) we obtain an adjunction between the full subcategory of spectral vector bundles $QVBun_\Sigma$ and the category of linearized locales $\text{LinLoc}$, which restricts to an equivalence of categories between sober spectral vector bundles and spatial linearized locales. The spectral vector bundles are classified by a finer topology on $\text{Sub} \ A$, called the open support topology, but there is no notion of universal spectral vector bundle for an arbitrary topological vector space $A$.

1. Introduction

A quotient vector bundle $[22]$ over a topological space $X$ is a triple $(\pi, A, q)$ that consists of a fiberwise linear quotient of a trivial complex vector bundle $\pi_2 : A \times X \to X$ by an open map $q$, where $A$ can be any complex topological vector space:

$$
\begin{array}{ccc}
A \times X & \xrightarrow{q} & E \\
\pi_2 \downarrow & & \downarrow \pi \\
X & \xleftarrow{\pi} &
\end{array}
$$

The continuous and open map $\pi : E \to X$ is then a topological vector bundle of a very general kind, which in particular does not have to be locally trivial and can have variable or infinite rank.

Such a bundle has enough sections in the sense that for any $e \in E$ there is a continuous section $s : X \to E$ such that $e = s(\pi(e))$; for each $e = q(a, \pi(e))$ just take $s$ to be the...
section \( q \) defined by \( q(a, x) = \hat{a}(x) \) for all \( x \in X \). As an example, any Banach bundle \( \pi : E \to X \) on a locally compact Hausdorff space \( X \) can be made a quotient vector bundle by taking \( A \) to be the space \( C_0(\pi) \) of continuous sections that vanish at infinity, with the supremum norm topology, where \( q : C_0(X) \times X \to E \) is the evaluation map \( q(s, x) = \text{eval}(s, x) = s(x) \).

Quotient vector bundles are classified by continuous maps \( \kappa : X \to \text{Sub} A \), where \( \text{Sub} A \) is the set of all the linear subspaces of \( A \) topologized with the lower Vietoris topology [16, 26] (with subclasses of bundles being classified by finer topologies such as the Fell topology). We shall refer to \( \text{Sub} A \) as the spectrum of the topological vector space \( A \). An aspect of \( \text{Sub} A \) has been ignored in [22], namely its complete lattice structure, which has an important role to play. In order to introduce this idea, for each continuous section \( s \) of \( \pi \) let us write \( \text{supp}^\circ s \) to denote the interior of the support of \( s \),

\[
\text{supp}^\circ s = \text{int}\{x \in X \mid s(x) \neq 0\},
\]

and let us consider two maps,

\[
\sigma : \text{Sub} A \to \Omega(X) ,
\gamma : \Omega(X) \to \text{Sub} A ,
\]

respectively called support map and restriction map, where \( \Omega(X) \) is the topology of \( X \). These maps are defined, for all \( V \in \text{Sub} A \) and \( U \in \Omega(X) \), by

\[
\sigma(V) = \bigcup_{a \in V} \text{supp}^\circ \hat{a} ;
\gamma(U) = \{a \in A \mid \text{supp}^\circ \hat{a} \subset U\}.
\]

The topology \( \Omega(X) \) is another complete lattice under inclusion of open sets, and it is clear that we have an equivalence

\[
\sigma(V) \subset U \iff V \subset \gamma(U)
\]

for all \( V \in \text{Sub} A \) and \( U \in \Omega(X) \). This means that the support map is left adjoint to the restriction map, and it immediately follows that they preserve suprema and infima, respectively:

\[
\sigma(\text{span}\bigcup_{\alpha} V_\alpha) = \bigcup_{\alpha} \sigma(V_\alpha) ,
\gamma(\text{int}\bigcap_{\alpha} U_\alpha) = \bigcap_{\alpha} \gamma(U_\alpha) .
\]

We shall regard the triple \((A, \sigma, \gamma)\) as a structure on the locale \( \Omega(X) \) in its own right, and, accordingly, we shall define the notion of linearized locale \( \mathfrak{A} = (\Delta, A, \sigma, \gamma) \) to consist of a locale \( \Delta \) together with a topological vector space \( A \) and a map \( \sigma : \text{Sub} A \to \Delta \).
with right adjoint $\gamma$, such that the restriction of $\gamma$ to the prime spectrum $\Sigma(\Delta)$ of $\Delta$ is a continuous map into $\text{Sub} \, A$. The latter means that the restricted map is the kernel map of a quotient vector bundle $\Sigma(\mathfrak{A})$, which we regard as a linear generalization of the spectrum of the locale $\Delta$, and which, accordingly, we refer to as the *spectrum* of $\mathfrak{A}$ (see [1] for analogous terminology whereby a line bundle is the spectrum of a C*-category). The spectrum $\Sigma(\mathfrak{A})$ will be seen to be a quotient vector bundle of a special kind, in particular such that for all $a \in A$ the set
\[ \{ p \in \Sigma(\Delta) \mid \hat{a}(p) \neq 0 \} \]
is open and thus coincides with the open support $\text{supp}^o \hat{a}$.

We shall see that from each quotient vector bundle $\mathcal{A} = (\pi : E \to X, A, q)$ we obtain a linearized locale $\Omega(\mathcal{A}) = (\Omega(X), A, \sigma, \gamma)$ as described above provided that the above openness condition holds with $\Delta = \Omega(X)$ for all $a \in A$, together with an additional continuity condition related to the spectrum of the locale $\Omega(X)$: the restriction of $\gamma$ to the prime spectrum $\Sigma \Omega(X)$ must be continuous. Hence, such quotient vector bundles will be termed *spectral (quotient) vector bundles*.

We shall also compare spectral vector bundles and linearized locales by looking at $\Sigma \Omega(\mathcal{A})$ and $\Omega \Sigma(\mathfrak{A})$ for each spectral vector bundle $\mathcal{A}$ and each linearized locale $\mathfrak{A}$. In some cases we may obtain $\mathcal{A} \cong \Sigma \Omega(\mathcal{A})$ and $\mathfrak{A} \cong \Omega \Sigma(\mathfrak{A})$ according to obvious notions of isomorphism, but this leaves out many examples which, despite not yielding such isomorphisms, nevertheless ought to be comparable. Hence, in order to obtain a more satisfactory understanding of how quotient vector bundles and linearized locales relate, we shall define appropriate notions of morphism for both. In particular, our morphisms of bundles will differ from typical morphisms of vector bundles, which usually consist of pairs of maps $(f_0, f_1)$ that yield commutative squares
\[
\begin{array}{ccc}
F & \xrightarrow{f_1} & E \\
\rho \downarrow & & \downarrow \pi \\
Y & \xrightarrow{f_0} & X
\end{array}
\]
but do not behave well with respect to global sections unless restrictions are imposed, such as local triviality of the bundles and requiring $f_1$ to be fiberwise a homeomorphism (as in [25] for maps of fiber bundles). The morphisms in this paper subsume the latter and will still be such that a morphism $f : \rho \to \pi$ yields a contravariant linear map $f^* : C(\pi) \to C(\rho)$ on the spaces of global sections that in the case of trivial line bundles agrees with the contravariant Gelfand duality functor. This property enables us to obtain an adjunction between the category of spectral vector bundles and that of linearized locales, where $\Omega$ is left adjoint to $\Sigma$, which extends the classical adjunction between topological spaces and locales whereby the topology functor $\Omega$ is left adjoint to the spectrum functor $\Sigma$ [9]. Similarly to classical locale theory, we shall find corresponding notions of spatial linearized locale and of sober spectral vector bundles, and conclude that their respective categories are equivalent.
At the end of the paper we also show that the spectral vector bundles on suitable topological spaces $X$ (for instance sober spaces) are classified by the continuous maps $\kappa : X \to \text{Sub}^0 A$, where $\text{Sub}^0 A$ is the set $\text{Sub} A$ with a topology herein called the \textit{open support topology}, which sits between the lower Vietoris and the Fell topologies. However, for other spaces $X$ the quotient vector bundles that correspond to continuous maps $\kappa : X \to \text{Sub}^0 A$ may fail to be spectral. In particular, in general there is no notion of universal spectral vector bundle for an arbitrary topological vector space $A$. In order to obtain some of these results we study the prime open sets of various topologies on $\text{Sub} A$, in particular yielding a result of interest in its own right, namely that if $A$ is a locally convex space then $\text{Max} A$, the space of closed linear subspaces of $A$ with the lower Vietoris topology, is a sober space.

Linearized locales are “quotient vector bundles on locales”. We note that this is not a full-fledged localic notion, since it is formulated in terms of topological vector spaces. It is in principle possible to give a fully localic definition by considering localic vector spaces instead, and subsequently defining $\text{Sub} A$ or $\text{Max} A$ to be a localic sup-lattice as in [23]. However, we are not following such an approach, at least for now, because the motivation for our project stems from questions related to $C^*$-algebras that we want to address without transforming them into questions about localic $C^*$-algebras. Moreover, this choice will enable us to take advantage of quantale theory, without first having to develop a theory of localic quantales, when studying linearized locales $(\Omega(G), A, \sigma, \gamma)$ such that $G$ is an open or étale groupoid and $A$ is a $C^*$-algebra, in which case both $\text{Max} A$ and $\Omega(G)$ are quantales [14, 15, 11, 21, 18].

In a subsequent paper it will be seen that such linearized locales arise in connection with $C^*$-algebras of groupoids [17]. In the case of an étale groupoid $G$ the space of units $G_0$ is open, and we obtain a pair $(A, B)$ consisting of the reduced $C^*$-algebra $A = C^*_r (G)$ and a sub-$C^*$-algebra $B = \gamma(G_0)$. More generally, this remains true for the reduced $C^*$-algebra $C^*_r (E)$ obtained from sections of a Fell bundle $E$ on $G$ in the sense of [12]. For Fell line bundles on suitable groupoids these sub-$C^*$-algebras are commutative and have been characterized precisely by Renault [20] (see also [13, 19, 6]). A partial generalization to noncommutative subalgebras is due to Exel [5] and it is formulated in terms of inverse semigroup Fell bundles [24], whose relation to groupoid Fell bundles has been studied in [3] in the semiabelian case, and, more recently, in [4]. The motivation for the present paper stems from the above program, in an attempt to provide general constructions via which the limitation to étale groupoids can be circumvented at least partially.

We thank the referee for his careful comments, which helped improve the presentation of this paper.

2. Preliminaries on vector bundles

We recall basic definitions from [22] in order to fix terminology and notation. Throughout this paper all the vector spaces are over $\mathbb{C}$, and topological vector spaces satisfy no specific topological properties unless otherwise stated. Topological vector spaces satisfying the $T_1$
axiom are necessarily Hausdorff (in fact completely regular), and we refer to them as Hausdorff vector spaces. Such a space is finite dimensional if and only if it is locally compact, in which case it necessarily has the Euclidean topology. We denote by Vect (resp. TopVect) the category of vector spaces (resp. topological vector spaces) and linear maps (resp. continuous linear maps). Given a subset \( S \subset A \) of a vector space \( A \) we denote the linear span of \( S \) by \( \text{span} S \), and if \( S \) is a finite set \( \{a_1, \ldots, a_k\} \) we also write \( \langle a_1, \ldots, a_k \rangle \) instead of \( \text{span}\{a_1, \ldots, a_k\} \).

2.1. Linear bundles.

**Basic facts and definitions.** Let \( \pi : E \to X \) be a continuous map between topological spaces \( E \) and \( X \). For each \( x \in X \) we refer to the set \( \pi^{-1}(\{x\}) \) as the fiber over \( x \) and denote it by \( E_x \).

By a linear structure on \( \pi \) will be meant a structure of vector space on each fiber \( E_x \) such that the operations of scalar multiplication and vector addition are globally continuous when regarded as maps \( \mathbb{C} \times E \to E \) and \( E \times_X E \to E \), respectively, and such that the zero section of \( \pi \), which sends each \( x \in X \) to \( 0_x \) (the zero of \( E_x \)) is continuous. Hence, \( \pi \) equipped with a linear structure is a very loose form of vector bundle, which we refer to as a linear bundle, the map \( \pi \) itself being called its projection.

The set \( C(\pi) \) of continuous sections of \( \pi \) is a vector space with the pointwise linear structure. The bundle is said to have enough sections if the evaluation map \( \text{eval} : C(\pi) \times X \to E \) is surjective.

If \( A \) is a topological vector space, the projection \( \pi_2 : A \times X \to X \) will be called a trivial linear bundle. Its space of continuous sections, \( C(\pi_2) \), is linearly isomorphic to the vector space of continuous functions \( C(X; A) \).

**Pullbacks.** Let \( \pi : E \to X \) be a linear bundle, and let
\[
f : Y \to X
\]
be a continuous map. The pullback of \( \pi \) along \( f \) defines a linear bundle
\[
f^*(\pi) = f^*(E) \to Y,
\]
where \( f^*(E) \) will usually be taken concretely to be the fibered product
\[
E \times_X Y = \{(e, y) \in E \times Y \mid \pi(e) = f(y)\},
\]
and \( f^*(\pi) = \pi_2 \). The pullback along \( f \) induces contravariantly a linear map on continuous sections,
\[
s \mapsto f^*(s) : C(\pi) \to C(\pi_2),
\]
by, for all \( s \in C(\pi) \) and \( y \in Y \),
\[
f^*(s)(y) = (s(f(y)), y).
\]
**Morphisms over fixed base space.** The category $\text{LinBun}(X)$ of linear bundles over $X$ has as morphisms

$$(\rho : F \to X) \xrightarrow{f} (\pi : E \to X)$$

the continuous and fiberwise linear maps $f : F \to E$ that commute with the projections:

```
F \xrightarrow{f} E
| \downarrow \rho \quad \downarrow \pi
\downarrow \quad \downarrow
X
```

Such a morphism induces a linear map $s \mapsto f_*(s) : C(\rho) \to C(\pi)$ by postcomposition: $f_*(s) = f \circ s$.

**2.2. Quotient vector bundles.**

**Basic definition and facts.** By a *quotient vector bundle* is meant a triple $\mathcal{A} = (\pi, A, q)$ where $\pi : E \to X$ is a linear bundle, $A$ is a topological vector space, and $q$ is a continuous open surjection that defines a morphism in $\text{LinBun}(X)$:

```
A \times X \xrightarrow{q} E
| \downarrow \pi_x \quad \downarrow \pi
\downarrow \quad \downarrow
X
```

For each $x \in X$ we denote by $q_x : A \to E_x$ the continuous map defined for all $a \in A$ by

$$q_x(a) = q(a, x) .$$

This is a continuous open linear surjection, and thus every fiber $E_x$ is a quotient of $A$ as a topological vector space. Moreover, the quotient topology on $E_x$ coincides with the relative topology of $E_x$ as a subspace of $E$.

**Sections.** For each $a \in A$ we have a continuous section of $\pi$,

$$\hat{a} : X \to E ,$$

which is defined for all $x \in X$ by

$$\hat{a}(x) = q(a, x) .$$

Every $e \in E$ is of this form, and thus quotient vector bundles have enough sections. The map $(-) : A \to C(\pi)$ thus defined is linear, and therefore its image $\hat{A}$ with the quotient topology is a quotient topological vector space of $A$. The kernel of the quotient map is the *radical of $\mathcal{A}$*:

$$\text{rad } \mathcal{A} = \bigcap_{x \in X} \ker q_x .$$
### Pullbacks

If $Y$ is a topological space and $f : Y \to X$ is a continuous map, the *pullback* $f^*(\mathcal{A})$ is the quotient vector bundle $(f^*(\pi), A, f^*(q))$ such that for all $a \in A$ and $y \in Y$ the continuous open surjection $f^*(q) : A \times Y \to E \times_X Y$ is defined by

$$f^*(q)(a, y) = (q(a, f(y)), y).$$

Equivalently, $f^*(q)$ is the unique map that makes the following diagram commute:

\[
\begin{array}{ccc}
A \times Y & \xrightarrow{id \times f} & A \times X \\
\downarrow{f^*(q)} & & \downarrow{q} \\
E \times_X Y & \xrightarrow{f^*(\pi)} & E \\
\downarrow{\pi_2} & & \downarrow{\pi_1} \\
Y & \xrightarrow{f} & X \\
\end{array}
\]

### Classifying spaces and universal bundles

We denote by $\text{Sub} A$ the collection of all the linear subspaces of $A$ topologized with the lower Vietoris topology [16, 26, 22], which is generated by the sub basis whose open sets are, for each open set $U \subset A$,

$$\tilde{U} = \{ P \in \text{Sub} A \mid P \cap U \neq \emptyset \}.$$

We refer to $\text{Sub} A$ as the *spectrum* of $A$. The *kernel map* of $\mathcal{A}$ is the continuous map

$$\kappa : X \to \text{Sub} A$$

which is defined for all $x \in X$ by $\kappa(x) = \ker q_x$.

Quotient vector bundles are classified by their kernel maps: from any continuous map

$$\kappa : X \to \text{Sub} A$$

we obtain a quotient vector bundle $(\pi : E \to X, A, q)$ such that $E$ is the quotient of $A \times X$ by the equivalence relation $\sim$ which is defined for all $x, y \in X$ and $a, b \in A$ by

$$(a, x) \sim (b, y) \iff (x = y \text{ and } a - b \in \kappa(x)).$$

Then $q : A \times X \to E$ is the quotient map and $\pi$ is the factorization of $\pi_2 : A \times X \to X$ through $q$. The kernel map of this bundle is $\kappa$.

If $\kappa : X \to \text{Sub} A$ is the kernel map of a quotient vector bundle $(\pi : E \to X, A, q)$ the construction just described yields a quotient vector bundle $(\pi' : E' \to X, A, q')$ such that $\pi$ is isomorphic to $\pi'$ in $\text{LinBun}(X)$ via an isomorphism $i : E \to E'$ that also commutes with $q$ and $q'$.

Finally we refer to the bundle obtained in this way from the identity map $\iota : \text{Sub} A \to \text{Sub} A$ as the *universal quotient vector bundle for $A$*, and denote it by $UA = (\pi_A : EA \to \text{Sub} A, A, q_A)$. Every quotient vector bundle for $A$ arises, up to an isomorphism as just described, as the pullback of $UA$ along the kernel map of the bundle.
3. Categories of vector bundles

In this section we study morphisms, over variable base space, of linear bundles and of quotient vector bundles, keeping in mind the general aim of obtaining a contravariant global sections functor.

3.1. CONTRAVARIANT MORPHISMS OF LINEAR BUNDLES.

**Covariant morphisms.** Let $\rho : F \to Y$ and $\pi : E \to X$ be linear bundles. There is more than one way in which to define a morphism from $\rho$ to $\pi$. An obvious choice is to let a morphism consist of a pair $(f_0, f_1)$ of continuous maps $f_0 : Y \to X$ and $f_1 : F \to E$ such that the following diagram commutes and $f_1$ is fiberwise linear:

\[
\begin{array}{ccc}
F & \xrightarrow{f_1} & E \\
\rho \downarrow & & \downarrow \pi \\
Y & \xrightarrow{f_0} & X
\end{array}
\]

We call such a morphism *covariant*, and composition is defined by $(g_0, g_1) \circ (f_0, f_1) = (g_0 \circ f_0, g_1 \circ f_1)$.

The sections of the bundles do not behave well with respect to such morphisms unless further conditions are imposed, as in the following example:

3.2. Example. Let $\rho : F \to Y$ and $\pi : E \to X$ be locally trivial vector bundles with the same constant finite rank, and let $(f_0, f_1) : \rho \to \pi$ be a covariant morphism such that $f_1$ is fiberwise a homeomorphism. Then a pullback map on sections $C(\pi) \to C(\rho)$ is obtained as in general for maps of coordinate bundles (cf. [25, Lem. 2.11]) by assigning to each $s \in C(\pi)$ the section $s' \in C(\rho)$ such that $s'(y) = f_y^{-1}(s(f_0(y)))$ for all $y \in Y$, where $f_y : E_y \to E_{f_0(y)}$ is the restriction of $f_1$ to $E_y$.

In general a pushforward map does not exist:

3.3. Example. Let $\rho : F \to Y$ and $\pi : E \to X$ be locally trivial vector bundles with the same constant finite rank, and let $\rho = \pi_1 : F = Y \times \mathbb{C} \to Y$ be the trivial line bundle over $Y$. Then $\mathbb{C} \setminus \{0\}$ acts on $F$ by multiplication, $\lambda \cdot (z_1, z_2, z_3) = (\lambda z_1, \lambda z_2, \lambda z_3)$, and similarly on $Y$. Denoting the quotients by these actions by

\[
\begin{align*}
f_1 : F &\to \mathbb{C}P^2 \setminus \{[0, 0, 1]\} \\
f_0 : Y &\to \mathbb{C}P^1
\end{align*}
\]

we obtain a covariant morphism $(f_0, f_1)$ from $\rho$ to the Hopf line bundle

\[
\pi : \mathbb{C}P^2 \setminus \{[0, 0, 1]\} \to \mathbb{C}P^1.
\]

The latter is nontrivial line bundle, so every section of $\pi$ has at least one zero. Since $f_1$ is fiberwise a homeomorphism and $\rho$ has nowhere vanishing sections, there can be no induced map from the sections of $\rho$ to the sections of $\pi$. 

A way to understand the relation of covariant morphisms to sections is to note that \( f_1 \) determines a unique continuous map \( f'_1 \) that makes the following diagram commute:

\[
\begin{array}{ccc}
F & \xrightarrow{f_1} & E \\
\searrow & \downarrow & \searrow \\
E \times_X Y & \xrightarrow{\pi_1} & E \\
\downarrow^{\pi_2} & & \downarrow^\pi \\
Y & \xrightarrow{f_0} & X
\end{array}
\]

The map \( f'_1 \) is a morphism in \( \text{LinBun}(Y) \) and, conversely, any such \( f'_1 \) defines a map \( f_1 \) such that \( (f_0, f_1) \) is a covariant morphism. Hence, \( (f_0, f_1) \) could have been defined equivalently to be the pair \( (f_0, f'_1) \). The map \( f'_1 \) yields a linear map \( (f'_1)_*: C(\rho) \to C(\pi_2) \) on sections, whereas the pullback gives us a linear map \( f_0^*: C(\pi) \to C(\pi_2) \). So in general we do not have a map relating \( C(\rho) \) and \( C(\pi) \). But this discussion shows that a natural way of obtaining a pullback of sections along \( f_0 \) is, instead of placing strong constraints on the bundles and on \( f_1 \) as in Example 3.2, simply to reverse the direction of \( f'_1 \), as we see next.

**Contravariant morphisms.** Let \( \rho : F \to Y \) and \( \pi : E \to X \) be linear bundles. By a contravariant morphism \( f : \rho \to \pi \) is meant a pair of continuous maps \( (f_\flat, f^\sharp) \) such that \( f^\sharp : f_\flat^*(\pi) \to \rho \) is a morphism in \( \text{LinBun}(Y) \), as follows:

\[
\begin{array}{ccc}
F & \xleftarrow{f^\sharp} & E \\
\downarrow^\rho & & \downarrow^\pi \\
E \times_X Y & \xleftarrow{\pi_1} & E \\
\searrow^{\pi_2} & & \searrow^\pi \\
Y & \xleftarrow{f_\flat} & X
\end{array}
\]

So fiberwise \( f^\sharp \) induces linear maps \( f^\sharp_y : E_{f_\flat(y)} \to F_y \) for each \( y \in Y \).

**3.4. Example.** If \( X \) and \( Y \) are smooth manifolds and \( E = T^*_X \), \( F = T^*_Y \) are the (complexified) cotangent bundles, any smooth map \( f_\flat : Y \to X \) induces a contravariant morphism \( (f_\flat, f^\sharp) \) with \( f^\sharp = f_\flat^* \).

In order to compose contravariant morphisms one should think of the pair \( (f^\sharp, \pi_1) \) as a “binary relation” between \( F \) and \( E \) (a span), and composition should be defined accordingly as composition of spans by pullback:
Although composition of spans is in general defined only up to isomorphism, there is a definition for contravariant morphisms which is associative “on the nose”. Let \( \sigma : G \rightarrow Z \), \( \rho : F \rightarrow Y \), and \( \pi : E \rightarrow X \) be linear bundles, with contravariant morphisms as follows:

\[
\begin{align*}
& \sigma \xrightarrow{g} \rho \xrightarrow{f} \pi
\end{align*}
\]

Then the composition \( f \circ g \) is the pair \((f \circ g, (f \circ g)^z)\), where \((f \circ g)^z : E \times_X Z \rightarrow G\) is defined, for all \( e \in E \) and \( z \in Z \), by

\[
(f \circ g)^z(e, z) = g^z(f^z(e, g_b(z)), z).
\]  
(3.1)

We note that this definition depends on all the four continuous maps involved. This is explicit in (3.1) for \(g_b\), \(g^z\), and \(f^z\), and the dependence on \(f_b\) is via the definition of the pullback \(E \times_X Z\):

\[
\begin{array}{ccc}
E \times_X Z & \xrightarrow{\pi_1} & E \\
\downarrow \pi_2 & & \downarrow \pi \\
Z & \xrightarrow{f \circ g_b} & X
\end{array}
\]

It is now straightforward to verify that the composition is associative and that the following identity morphism on \(\pi : E \rightarrow X\) is a neutral element for composition both on the right and on the left:

\[
\text{id}_\pi = (\text{id}_X, \pi_1 : E \times_X X \xrightarrow{\cong} E).
\]

We denote the resulting category by \(\text{LinBun}\). A morphism \(f\) is an isomorphism in this category if and only if both \(f_b\) and \(f^z\) are homeomorphisms. Note that there is always a contravariant morphism \((f, \text{id}) : f^*(\pi) \rightarrow \pi\).

We remark that for each topological vector space \(A\) there is a faithful functor \(B_A : \text{Top} \rightarrow \text{LinBun}\) that to each topological space \(X\) assigns the trivial bundle

\[
B_A(X) = \pi_2 : A \times X \rightarrow X
\]

and to each continuous map \(f : Y \rightarrow X\) assigns the contravariant morphism

\[
B_A(f) = (f, (A \times X) \times_X Y \xrightarrow{\cong} A \times Y).
\]

**Functoriality of sections.** Let \(\rho : F \rightarrow Y\) and \(\pi : E \rightarrow X\) be linear bundles, and \(f : \rho \rightarrow \pi\) a contravariant morphism. The composition

\[
\hat{f} := f^z \circ f_b^* : C(\pi) \rightarrow C(\rho)
\]

is a linear map, and thus we have a contravariant functor

\[
C : \text{LinBun}^{\text{op}} \rightarrow \text{Vect}
\]
defined on linear bundles \( \pi \) and contravariant morphisms \( f \) by
\[
\begin{align*}
\pi &\mapsto C(\pi), \\
f &\mapsto \hat{f}.
\end{align*}
\]
This generalizes, for each topological vector space \( A \), the contravariant functor
\[
C(-; A) : \text{Top}^{\text{op}} \to \text{Vect}
\]
in the sense that \( C(-; A) = C \circ B_A \).

**3.5. Example.** Let \( \rho : F \to Y \) and \( \pi : E \to X \) be locally trivial vector bundles with the same constant finite rank, and let \((f_0, f_1) : \rho \to \pi\) be a covariant morphism such that \( f_1 \) is fiberwise a homeomorphism. Then a contravariant morphism \( f = (f_0, f^*_0) \) is obtained by setting \( f_0 = f_0 \) and \( f_0^*(e, y) = f_1^{-1}(e) \) for all \((e, y) \in E \times_X Y\), where \( f_y : E_y \to E_{f(y)} \) is the restriction of \( f_1 \) to \( E_y \), and the continuity of \( f^*_0 \) follows from local triviality. The map \( \hat{f} \) is the same as the maps of sections in Example 3.2.

We note that if \( f : \rho \to \pi \) is a morphism in \( \text{LinBun} \) and \( \pi \) has enough sections then \( f^* \) is uniquely determined by \( f_0 \) and \( \hat{f} \), since for all \((e, y) \in E \times_Y Y \) we have \( e = s(f_0(y)) \) for some \( s \in C(\pi) \) and
\[
f^*(e, y) = f_0^*(s(f_0(y)), y) = f_0^*(f_0^*(s))(y) = \hat{f}(s)(y) .
\] (3.2)

A similar phenomenon occurs in sheaf theory, where the notion of cohomomorphism for sheaves of vector spaces is equivalent to that of contravariant morphism between étale linear bundles, as we show in the following example.

**3.6. Example.** Let the linear bundles \( \rho : F \to Y \) and \( \pi : E \to X \) be local homeomorphisms, and let \( f : \rho \to \pi \) be a contravariant morphism. The map on sections \( \hat{f} \) applies equally to local sections, so for each continuous local section \( s : U \to E \) of \( \pi \) we obtain a continuous local section \( \hat{f}(s) : f_0^{-1}(U) \to F \) of \( \rho \). This property means that \( f_0 \) together with the induced maps on the fibers \( f_y^* : E_{f(y)} \to F_y \) is a cohomomorphism of sheaves [2].

Conversely, from any cohomomorphism \((f_0, f_0^*_y)_{y \in Y}\) with linear fiber maps \( f_0^*_y \) we obtain a contravariant morphism such that \( f^* \) is given by \( f^*(e, y) = f_0^*(e) \) and is easily seen to be continuous due to the existence of enough continuous local sections and the fact that for a local homeomorphism the local sections are open maps: if \( U \subset F \) is open we have, writing \( s \) generically for a local section of \( \pi \),
\[
(f^*)^{-1}(U) = \{ (e, y) \in E \times_X Y \mid f_0^*(e) \in U \}
= \bigcup_s \{ (s(f_0(y)), y) \mid f_0^*(s(f_0(y))) \in U \}
= \bigcup_s \{ f^*(s)(y) \mid \hat{f}(s)(y) \in U \}
= \bigcup_s f^*(s)(\hat{f}(s)^{-1}(U)),
\]
and this is open because \( \hat{f}(s) \) is continuous by hypothesis.
3.7. The category of quotient vector bundles.

Contravariant morphisms revisited. Let us look again at contravariant morphisms, now for linear bundles which are equipped with the additional structure of a quotient vector bundle. The notion of morphism which we are about to define can be regarded, in our context, as the natural adaptation of the notion of cohomomorphism (cf. Example 3.6).

Let $A = (\pi : E \to X, A, q)$ and $B = (\rho : F \to Y, B, r)$ be quotient vector bundles. By a morphism $f : B \to A$ will be meant a contravariant morphism of linear bundles $(f^\flat, f^\sharp) : \rho \to \pi$ whose induced map on sections $\hat{f} : C(\pi) \to C(\rho)$ satisfies

$$\hat{f}(\hat{A}) \subset \hat{B},$$

(3.3)

together with a continuous linear map $f^* : A \to B$ such that the following diagram commutes:

$$
\begin{array}{ccc}
\hat{B} & \xleftarrow{\hat{f}} & \hat{A} \\
\downarrow & & \downarrow \\
B & \xleftarrow{f^*} & A
\end{array}
$$

(3.4)

In particular, this implies the following condition on radicals:

$$f^*(\text{rad} A) \subset \text{rad} B.$$  

(3.5)

These morphisms form a category $QVBun$, which we refer to as the category of quotient vector bundles:

- The composition $f \circ g$ is the pair consisting of the contravariant morphism $(f^\flat, f^\sharp) \circ (g^\flat, g^\sharp)$ together with the continuous linear map $g^* \circ f^*$;

- The identity morphism on $A = (\pi : E \to X, A, q)$ is the identity contravariant morphism on $\pi$ together with $\text{id}_A$.

We note that a morphism $f$ in this category is an isomorphism if and only if its three components are homeomorphisms.

3.8. Lemma. Let $A = (\pi : E \to X, A, q)$ and $B = (\rho : F \to Y, B, r)$ be quotient vector bundles. If $f : B \to A$ is a morphism in $QVBun$ then $f^\sharp$ is uniquely defined for all $a \in A$ and $y \in Y$ by

$$f^\sharp(q(a, f^\flat(y))) = r(f^*(a), y).$$

Proof. For all $(e, y) \in E \times_X Y$ we have $e = \hat{a}(f^\flat(y))$ for some $a \in A$ and thus, by (3.2) and (3.4),

$$f^\sharp(q(a, f^\flat(y))) = f^\sharp(e, y) = \hat{f}(\hat{a})(y) = \hat{f}^*(a)(y) = r(f^*(a), y).$$

\[\square\]
There is a similar result when the map $B \to \widehat{B}$ is a homeomorphism: then the map $f^*$ is completely determined by the contravariant morphism $(f_\sharp, f^\sharp)$. In this case we can characterize the morphisms of quotient vector bundles as the contravariant morphisms of linear bundles which satisfy (3.3).

3.9. Example. As mentioned in section 1, from a Banach bundle over a locally compact Hausdorff space we can obtain a quotient vector bundle by taking $A$ to be the space $C_0(\pi)$ of sections which vanish at infinity with the supremum norm topology. In that case we have $A \cong \widehat{A}$. Given a contravariant morphism of Banach bundles $(f_\flat, f^\sharp): \rho \to \pi$, if $f_\flat$ is proper then $\widehat{(C_0(\pi))} \subset C_0(\rho)$, so we obtain a morphism of the associated quotient vector bundles. This applies in particular to Example 3.4 whenever $f_\flat$ is proper.

Equivalent definition of morphism. From Lemma 3.8 it follows that if $f = (f_\flat, f^\sharp, f^*)$ is a morphism of quotient vector bundles then the following condition, relating $f_\flat$ and $f^*$, must hold for all $a \in A$ and $y \in Y$:

\[
q(a, f_\flat(y)) = 0 \implies r(f^*(a), y) = 0.
\] (3.6)

There is a converse to this:

3.10. Lemma. Let $A = (\pi : E \to X, A, q)$ and $B = (\rho : F \to Y, B, r)$ be quotient vector bundles. Every pair of maps

\[
f_\flat : Y \to X \quad \text{(continuous)}
\]

\[
f^* : A \to B \quad \text{(continuous linear)}
\]

satisfying (3.6) arises from a morphism $f = (f_\flat, f^\sharp, f^*)$ in $QVBun$ for a unique map $f^\sharp$.

Proof. Condition (3.6) implies that we may define a fiberwise linear map

\[
f^\sharp : E \times_X Y \to F
\]

for all $y \in Y$ and $e \in E_{f_\flat(y)}$ by

\[
f^\sharp(e, y) = r(f^*(a), y),
\] (3.7)

where $a \in A$ is any element of $A$ such that $q(a, f_\flat(y)) = e$. In other words, $f^\sharp$ is the unique map that makes the following diagram commute:

\[
\begin{array}{ccc}
B \times Y & \xleftarrow{f^* \times \text{id}} & A \times Y & \xleftarrow{q \times \text{id}} & (A \times X) \times_X Y \\
\downarrow r & & \downarrow f^\sharp & & \downarrow q \times \text{id} \\
F & \xleftarrow{f^\sharp} & E \times_X Y
\end{array}
\]

Now $q \times \text{id}$ is a quotient map because it is open and surjective. Therefore $f^\sharp$ is continuous, and thus we have a contravariant morphism $(f_\flat, f^\sharp) : \rho \to \pi$. 

Next we show that the triple $f = (f_0, f^\sharp, f^*)$ is a morphism in $QVBun$. Let $a \in A$ and $y \in Y$. We have $\widehat{f} = f^\sharp \circ f^*$, and thus, letting $e = q(a, f_0(y))$ in (3.7), we obtain
\[
\widehat{f^*}(a)(y) = r(f^*(a), y) = f^\sharp(q(a, f_0(y)), y) = f^\sharp(\hat{a}(f_0(y)), y) = \widehat{f}(\hat{a})(y),
\]
showing that (3.4) holds.

Hence, we see that the morphisms of quotient vector bundles can be defined alternatively but equivalently to be pairs $(f_0, f^*)$ satisfying (3.6), with $f^\sharp$ being derived from the formula in Lemma 3.8:
\[
f^\sharp(q(a, f_0(y))) = r(f^*(a), y).
\]
This formula further implies that $f^\sharp$ is fiberwise injective if and only if for all $a \in A$ and $y \in Y$ we have
\[
q(a, f_0(y)) = 0 \iff r(f^*(a), y) = 0.
\]
(3.8)

A morphism of quotient vector bundles such that the above equivalence holds is called strict, whereas if only the implication (3.6) holds it is called lax. The strict morphisms yield a subcategory of quotient vector bundles, which we refer to as the strict category of quotient vector bundles, denoted by $sQVBun$.

3.11. Example. Let $\rho : F \to Y$ and $\pi : E \to X$ be locally trivial finite rank vector bundles over locally compact Hausdorff spaces, and let $(f_0, f_1)$ be a covariant morphism such that $f_0$ is a proper map and $f_1$ is fiberwise a homeomorphism. Then we obtain, by Example 3.5 and Example 3.9, a strict morphism of quotient vector bundles $(f_0, f^\sharp) : (\rho, C_0(\rho), \text{eval}) \to (\pi, C_0(\pi), \text{eval})$.

4. Preliminaries on pointfree topology

In this section we provide some background on sup-lattices and locales. More details can be found for instance in [10, 9].

4.1. Sup-lattices.

Basic definitions and examples. By a sup-lattice [10, Ch. I] will be meant a partially ordered set $L$ for which any subset $S$ has a join (supremum), which is denoted by $\bigvee S$ or $\text{sup } S$. Similarly, we write $\bigvee \alpha a_\alpha$ or $\text{sup } \alpha a_\alpha$ for the join of an indexed family $(a_\alpha)$ in $L$. Sup-lattices necessarily have meets (infima) of every subset (denoted by $\bigwedge S$ or $\text{inf } S$), but the terminology we adopt reflects (as opposed to “complete lattice”) the fact that joins are the first-class algebraic operations in the sense that they are preserved by homomorphisms $f : L \to M$:
\[
f(\bigvee S) = \bigvee f(S).
\]
The category of sup-lattices $SL$ is defined to have sup-lattices as objects and homomorphisms as arrows. Additionally, we adopt the usual notation from lattice theory for meets and joins of pairs of elements, writing $a \lor b$ and $a \land b$ instead of $\text{sup } \{a, b\}$ and $\text{inf } \{a, b\}$,
respectively, and writing $1_L$ and $0_L$, or simply 1 and 0 when no confusion will arise, respectively for the greatest element $\bigvee L = \bigwedge \emptyset$ and the least element $\bigwedge L = \bigvee \emptyset$ of a sup-lattice $L$.

As examples of sup-lattices we mention:

1. The topology $\Omega(X)$ of a topological space $X$, ordered by inclusion; we have $\bigvee S = \bigcup S$ for all $S \subset \Omega(X)$, and $\bigwedge S$ is the interior of $\bigcap S$. For binary meets we have $U \wedge V = U \cap V$.

2. The set of linear subspaces, $\text{Sub} A$, of a vector space $A$. If $(V_\alpha)$ is a family in $\text{Sub} A$ we have $\bigvee_\alpha V_\alpha = \text{span} \bigcup_\alpha V_\alpha$ and $\bigwedge_\alpha V_\alpha = \bigcap_\alpha V_\alpha$. Any linear map $f : A \to B$ between vector spaces yields a sup-lattice homomorphism $\text{Sub} f : \text{Sub} A \to \text{Sub} B$ defined by
   \[
   \text{Sub} f(V) = f(V),
   \]
   and in this way one obtains a functor $\text{Sub} : \text{Vect} \to SL$.

3. The set of closed linear subspaces, $\text{Max} A$, of a topological vector space $A$. If $(V_\alpha)$ is a family in $\text{Max} A$ we have $\bigvee_\alpha V_\alpha = \text{span} \bigcup_\alpha V_\alpha$ and $\bigwedge_\alpha V_\alpha = \bigcap_\alpha V_\alpha$. Any continuous linear map $f : A \to B$ between topological vector spaces yields a sup-lattice homomorphism $\text{Max} f : \text{Max} A \to \text{Max} B$ defined by
   \[
   \text{Max} f(V) = \overline{f(V)},
   \]
   and in this way one obtains a functor $\text{Max} : \text{TopVect} \to SL$.

**Adjunctions.** Let $L$ and $M$ be sup-lattices. We write $f \dashv g$ in order to indicate that $f$ is left adjoint to $g$:

\[
\begin{array}{ccc}
L & \xleftarrow{f} & M \\
\downarrow & \searrow \\downarrow & \searrow \\
g & &
\end{array}
\]

The pair $(f, g)$ will be referred to as an *adjunction from $L$ to $M$*.

4.2. **Example.** Let $A$ and $B$ be a complex vector spaces, and let $f : A \to B$ be a linear map. Recall that $\text{Sub} f$ is the sup-lattice homomorphism $\text{Sub} A \to \text{Sub} B$ defined by $\text{Sub} f(V) = f(V)$ for all $V \in \text{Sub} A$. The right adjoint of $\text{Sub} f$ is the inverse image map $f^{-1} : \text{Sub} B \to \text{Sub} A$, as the following equivalences show, where $V \in \text{Sub} A$ and $W \in \text{Sub} B$:

\[
\text{Sub} f(V) \subset W \iff f(V) \subset W \iff V \subset f^{-1}(W).
\]

We note that the bijection between sup-lattice homomorphisms and their right adjoints is an antitone order isomorphism with respect to the pointwise order on maps: if both $f \dashv g$ and $f' \dashv g'$ are adjunctions from $L$ to $M$ then we have $f \leq f' \iff g' \leq g$.

4.3. **Locales.**
Basic definitions and facts. A locale (see [9]) is a sup-lattice $L$ satisfying the distributivity property

$$a \land \bigvee_{\alpha} b_\alpha = \bigvee_{\alpha} a \land b_\alpha$$

for all $a \in L$ and all families $(b_\alpha)$ in $L$. The main example of a locale is the topology $\Omega(X)$ of a topological space.

A map of locales $f : M \to L$ is a homomorphism of sup-lattices in the opposite direction,

$$f^* : L \to M ,$$

that also preserves finite meets:

$$f^*(1_L) = 1_M,$$

$$f^*(a \land b) = f^*(a) \land f^*(b).$$

Then $f^*$ is called a homomorphism of locales, and it is referred to as the inverse image homomorphism of the map $f$. This terminology follows from the fact that every continuous map of topological spaces $\varphi : Y \to X$ defines a map of locales $f : \Omega(Y) \to \Omega(X)$ by the condition:

$$f^* = \varphi^{-1} : \Omega(X) \to \Omega(Y) .$$

The category of locales $Loc$ has the locales as objects and the maps of locales as arrows. The assignment $X \mapsto \Omega(X)$ extends to a functor

$$\Omega : Top \to Loc$$

such that for each continuous map $\varphi$ we have

$$(\Omega \varphi)^* = \varphi^{-1} .$$

We also note that, since the inverse image homomorphism of a map of locales $f : M \to L$ preserves joins, there is a meet preserving map (the right adjoint of $f^*$)

$$f_* : M \to L ,$$

which is defined by, for all $b \in M$,

$$f_*(b) = \bigvee \{a \in L \mid f^*(a) \leq b\} .$$

If $\varphi : Y \to X$ is a continuous open map between topological spaces then we denote by $\varphi! : \Omega(Y) \to \Omega(X)$ the direct image homomorphism defined by $\varphi!(U) = \varphi(U)$. This is a sup-lattice homomorphism, left adjoint to $\varphi^{-1} : \Omega(X) \to \Omega(Y)$. 
Points and prime elements. A point of a locale $L$ is usually defined to be a map $x : \Omega \to L$, where $\Omega = \wp(\{\star\})$ is the topology of a singleton. Although locale theory is often meant to be applied in a constructive setting (i.e., in an arbitrary topos), classically $\Omega$ is just a two element chain $\{0, 1\}$ with $0 < 1$, and the set of points $x$ is in bijective correspondence with the set of elements of the form

$$\bigvee \ker x^* = \bigvee \{a \in L \mid x^*(a) = 0\}.$$  

These elements are precisely the prime elements of $L$, where an element $p \in L$ of a locale $L$ is said to be prime if it satisfies the following two conditions for all $a, b \in L$:

$$\begin{align*}
p &\neq 1 \\
a \wedge b \leq p &\Rightarrow a \leq p \text{ or } b \leq p.
\end{align*}$$

For the purposes of this paper it will be useful to identify the points of a locale $L$ with its prime elements, and we denote the set of the latter by $\Sigma(L)$.

The following simple fact will be used later:

4.4. Lemma. Let $X$ be a topological space with a subbasis $S$. Any prime element $P \in \Omega X$ is a union of subbasic open sets.

Proof. For any $x \in P$ there are subbasic open sets $S_1, \ldots, S_k \in S$ such that $x \in S_1 \cap \cdots \cap S_k \subset P$. Since $P$ is prime, $x \in S_i \subset P$ for some $i$. 

The spectrum of a locale. For each $a \in L$, where $L$ is a locale, we define the following set,

$$U_a = \{p \in \Sigma(L) \mid a \not\approx p\},$$

and the following conditions hold:

$$\begin{align*}
U_1 &= \Sigma(L); \\
U_{a \wedge b} &= U_a \cap U_b; \\
U_{\bigvee a} &= \bigcup_\alpha U_{a_\alpha}.
\end{align*}$$

Hence, the collection $(U_a)_{a \in L}$ defines a topology $\Omega \Sigma(L)$ on $\Sigma(L)$. The set of primes equipped with this topology will be called the spectrum of the locale $L$. The assignment $a \mapsto U_a$ is a homomorphism of locales that defines a map of locales $\text{spat}_L : \Omega \Sigma(L) \to L$ called the spatialization of $L$. A locale is called spatial if its spatialization map is an isomorphism. This is equivalent to the statement that $L$ is isomorphic to the topology of some topological space.

The spectrum functor. If $f : M \to L$ is a map of locales we obtain a continuous map 

$$\Sigma(f) : \Sigma(M) \to \Sigma(L).$$
which coincides with the restriction of \( f_* \) to \( \Sigma(M) \):

\[
\Sigma(f)(p) = \bigvee \{ a \in L \mid f^*(a) \leq p \} .
\]

In this way we have a functor

\[ \Sigma : \text{Loc} \rightarrow \text{Top} , \]

which is right adjoint to \( \Omega \). If \( X \) is a topological space there is a continuous map \( \text{sob}_X : X \rightarrow \Sigma \Omega(X) \), called the \textit{soberification of} \( X \), which to each \( x \in X \) assigns the complement in \( X \) of the closure \( \overline{\{x\}} \). The space \( X \) is \( T_0 \) if and only if \( \text{sob}_X \) is injective. Moreover, note the following simple fact:

4.5. \text{Lemma}. \textit{If} \( \text{sob}_X \) \textit{is surjective then it is an open map.}

\text{Proof.} Let \( W \subset X \) be open. The condition \( \text{sob}_X(x) \in U_W \) is equivalent to \( x \in W \), so if \( \text{sob}_X \) is surjective we have \( \text{sob}_X(W) = U_W \).

It follows that if \( \text{sob}_X \) is bijective then it is necessarily a homeomorphism, and in this case \( X \) is said to be a \textit{sober space}. In particular, the spectrum of a locale is a sober space, and hence \( T_0 \).

The adjunction between \( \Omega \) and \( \Sigma \) restricts to an equivalence of categories between the full subcategories of spatial locales and sober spaces. If \( X \) is a Hausdorff space, the prime elements of \( \Omega(X) \) are exactly the open sets of the form \( X \setminus \{x\} \) and thus \( X \) is sober.

5. \text{Quotient vector bundles via locales}

The ideas described in the introduction show that a quotient vector bundle \( A = (\pi : E \rightarrow X, A, q) \) gives rise to an adjunction between \( \text{Sub} A \) and \( \Omega(X) \), both regarded as sup-lattices under the inclusion order. The left adjoint is the \textit{open support map} \( \sigma : \text{Sub} A \rightarrow \Omega(X) \), and the right adjoint \( \gamma : \Omega(X) \rightarrow \text{Sub} A \) yields, for each open set \( U \subset X \), the set of “formal sections” \( a \in A \) such that the open support \( \text{supp}^\circ \hat{a} \) is contained in \( U \). In this section we pursue this idea in order to study quotient vector bundles, in the end obtaining an adjunction between the category of such locales with linear structure and a subcategory of the category of quotient vector bundles. The objects of this category will be called \textit{spectral vector bundles}. Any quotient vector bundle on a sober base space and with closed zero section will be seen to be of this kind.

5.1. \text{Linearized locales.}

\textbf{Basic definitions and facts.} Let \( \triangle \) be a locale. By a \textit{linear structure} on \( \triangle \) is meant a topological vector space \( A \) together with a sup-lattice homomorphism

\[ \sigma : \text{Sub} A \rightarrow \triangle , \]

which we refer to as the \textit{support map}, and whose right adjoint \( \gamma : \triangle \rightarrow \text{Sub} A \) restricts to a continuous map \( \delta = \gamma|_{\Sigma(\triangle)} : \Sigma(\triangle) \rightarrow \text{Sub} A \). The map \( \gamma \) is referred to as the \textit{restriction}
map — for each \( U \in \triangle \) we may think of \( \gamma(U) \) as the restriction of \( A \) to \( U \), where \( A \) is regarded as a space of formal global sections on \( \triangle \). The map \( \mathfrak{k} \) is referred to as the kernel map of the linear structure.

By a linearized locale \( \mathfrak{A} = (\triangle, A, \sigma, \gamma) \) will be meant a locale \( \triangle \) equipped with a linear structure given by \( A \) and \( \sigma \), with \( \sigma \vdash \gamma \).

The continuity of the kernel map of a linear structure has the following necessary condition:

5.2. Lemma. Let \( \mathfrak{A} = (\triangle, A, \sigma, \gamma) \) be a linearized locale. For all \( p, q \in \Sigma(\triangle) \) the following implication holds:

\[
p \leq q \Rightarrow \gamma(p) = \gamma(q) .
\]

**Proof.** The specialization order of the topology of \( \Sigma(\triangle) \) is dual to the order of \( \triangle \). Hence, the kernel map, which is monotone because \( \gamma \) is, is also antitone on prime elements due to continuity, and thus the condition \( p \leq q \) implies that \( \gamma(p) \) and \( \gamma(q) \) are topologically equivalent, which for the lower Vietoris topology means precisely that their closures in \( A \) are the same. \[\blacksquare\]

We also mention, although we shall not use it in this paper, the following general necessary and sufficient condition for the continuity of the kernel map.

5.3. Theorem. Let \( \triangle \) be a locale, \( A \) a topological vector space, and \( \sigma \vdash \gamma \) an adjunction from \( \text{Sub} A \) to \( \triangle \). Then \( \mathfrak{k} := \gamma|_{\Sigma(\triangle)} \) is continuous if and only if for all open sets \( U \subset A \) the set \( \bigcap_{a \in U} U_{\sigma(\langle a \rangle)} \) is closed in \( \Sigma(\triangle) \).

**Proof.** Let \( U \subset A \) be an open set and \( p \in \Sigma(\triangle) \). Then

\[
p \in \mathfrak{k}^{-1}(\tilde{U}) \iff \mathfrak{k}(p) \cap U \neq \emptyset \]
\[
\iff \exists a \in U \ a \in \mathfrak{k}(p) \]
\[
\iff \exists a \in U \ \langle a \rangle \subset \gamma(p) \]
\[
\iff \exists a \in U \ \sigma(\langle a \rangle) \leq p \]
\[
\iff \exists a \in U \ \sigma(\langle a \rangle) \leq p \]
\[
\iff \exists a \in U \ p \notin U_{\sigma(\langle a \rangle)} \]
\[
\iff \exists a \in U \ p \notin \bigcap_{a \in U} U_{\sigma(\langle a \rangle)} ,
\]

and thus \( \mathfrak{k}^{-1}(\tilde{U}) = \Sigma(\triangle) \setminus \bigcap_{a \in U} U_{\sigma(\langle a \rangle)} \). Hence, \( \mathfrak{k} \) is continuous if and only if \( \bigcap_{a \in U} U_{\sigma(\langle a \rangle)} \) is closed for all \( U \in \Omega(A) \). \[\blacksquare\]

**Morphisms of linearized locales.** Let the following be linearized locales:

\[
\mathfrak{A} = (A, \triangle_A, \sigma_A, \gamma_A),
\]
\[
\mathfrak{B} = (B, \triangle_B, \sigma_B, \gamma_B).
\]

A morphism \( \mathfrak{f} : \mathfrak{B} \rightarrow \mathfrak{A} \) is a pair \((\mathfrak{f}, \mathfrak{f})\) consisting of a map of locales

\[
\mathfrak{f} : \triangle_B \rightarrow \triangle_A
\]
and a continuous linear map 
\[ \overline{f} : A \to B \]
satisfying, for all \( V \in \text{Sub} A \), the inclusion
\[ \sigma_B(\overline{f}(V)) \subset f^*(\sigma_A(V)) . \quad (5.1) \]
In other words, \( \overline{f} \) satisfies the following lax commutation relation:
\[ \text{Sub} A \xrightarrow{\sigma_A} \text{Sub} B \xleftarrow{\triangle_A} \text{Sub} A \]
\[ \text{Sub} B \xleftarrow{\sigma_B} \text{Sub} B \xrightarrow{\triangle_B} \text{Sub} B \]  
\[ \triangle_A f^* \xrightarrow{\sigma_B} \triangle_B \]  

Equivalently, on right adjoints, recalling that the right adjoint of \( \text{Sub} \overline{f} \) coincides with \( \overline{f}^{-1} \), we have:
\[ \text{Sub} A \xleftarrow{\gamma_A} \text{Sub} B \xrightarrow{\gamma_B} \text{Sub} B \]
\[ \text{Sub} A \xrightarrow{\overline{f}^{-1}} \text{Sub} B \xleftarrow{\gamma_B} \text{Sub} B \]  
\[ \triangle_A \xrightarrow{\triangle_B} \]  

These morphisms yield an obvious category \( \text{LinLoc} \), which we shall refer to as the category of linearized locales (with lax morphisms). By requiring the above commutation relations to be strict we obtain the subcategory \( s\text{LinLoc} \), referred to as the strict category of linearized locales. Natural examples of such morphisms can be obtained from Example 3.9 via the adjunction that will be obtained later in this section.

5.4. Spectral vector bundles.

The spectral kernel of a quotient vector bundle. Let \( A = (\pi : E \to X, A, q) \) be a quotient vector bundle with kernel map \( \kappa : X \to \text{Sub} A \), and consider the adjoint pair
\[ \text{Sub} A \xleftarrow{\gamma} \Delta \]
\[ \text{Sub} A \xrightarrow{\sigma} \Delta \]
where \( \sigma \) and \( \gamma \) are defined by
\[ \sigma(V) = \bigcup_{a \in V} \text{supp}^\circ \hat{a} , \]
\[ \gamma(U) = \{a \in A \mid \text{supp}^\circ \hat{a} \subset U\} . \]
The restriction of \( \gamma \) to the set of prime open sets of \( X \),
\[ \varepsilon := \gamma|_{\Sigma(\Delta)} : \Sigma(\Delta) \to \text{Sub} A , \]
will be referred to as the spectral kernel map of the bundle \( A \). Then we have the following immediate remark:
5.5. Lemma. $(\Omega(X), A, \sigma, \gamma)$ is a linearized locale if and only if the spectral kernel $\kappa$ of $A$ is continuous.

Also, note the following relation between the two kernel maps:

5.6. Lemma. For all $x \in X$ we have $\kappa(x) \subset \tilde{k}(\text{sob } x)$.

Proof. We have $\kappa(x) = \{\hat{a} \in A \mid \hat{a}(x) = 0\}$ and $\tilde{k}(\text{sob } x) = \tilde{k}(X \setminus \{x\}) = \{a \in A \mid x \notin \text{supp}^\circ \hat{a}\}$, and also $\hat{a}(x) = 0 \Rightarrow x \notin \text{supp}^\circ \hat{a}$.

**Open support property.** In most examples that arise in practice, such as those obtained from Banach bundles, the (image of the) zero section of a quotient vector bundle is closed in $E$, and thus the sets $\{x \in X \mid \hat{a}(x) \neq 0\}$ are open, so that we have

$$\text{supp}^\circ \hat{a} = \{x \in X \mid \hat{a}(x) \neq 0\}.$$

We will say that the quotient vector bundle has the open support property if the above condition holds for all $a \in A$. As will be seen below, this property is in general weaker than having a closed zero section and it is useful in its own right.

The open support property can also be formulated equivalently in terms of the kernel maps $\kappa$ and $\tilde{k}$ of $A$, as we now show.

5.7. Lemma. $A$ has the open support property if and only if $\kappa = \tilde{k} \circ \text{sob}$. In particular, these equivalent conditions hold whenever the (image of the) zero section of $\pi$ is a closed set of $E$.

Proof. We have $\kappa = \tilde{k} \circ \text{sob}$ if and only if for all $a \in A$ and all $x \in X$ the following equivalence holds:

$$\hat{a}(x) = 0 \iff x \notin \text{supp}^\circ \hat{a}.$$

**Continuous spectral kernels.** We say that $A$ is a spectral (quotient) vector bundle if $A$ has the open support property and the spectral kernel $\kappa$ is continuous. The full subcategory of $QVBun$ (resp. $sQVBun$) whose objects are the spectral vector bundles is denoted by $QVBun_{\Sigma}$ (resp. $sQVBun_{\Sigma}$).

The following is a useful sufficient condition for spectrality:

5.8. Lemma. If a quotient vector bundle $A = (\pi : E \to X, A, q)$ has the open support property and $\text{sob} : X \to \Sigma \Omega(X)$ is surjective then $A$ is spectral.

Proof. The surjectivity of sob tells us that the direct image $\text{sob}_! : \Omega(X) \to \Omega \Sigma \Omega(X)$ is surjective (cf. Lemma 4.5). Therefore the inverse image map $\text{sob}^{-1}$ is injective and $\text{sob}_! \circ \text{sob}^{-1}$ is the identity map on $\Omega \Sigma \Omega(X)$. Hence,

$$\kappa^{-1} = \text{sob}_! \circ \text{sob}^{-1} \circ \kappa^{-1}.$$

and it follows that $\kappa$ is continuous.
5.9. Example. Any Banach bundle \( \pi : E \to X \) as in [8] has a Hausdorff base space \( X \) and a closed zero section, and thus any quotient vector bundle \( (\pi, A, q) \) is spectral. For instance, if \( X \) is locally compact we may take \( A = C_0(\pi) \) and \( q = \text{eval} \) [22].

5.10. Example. It is possible to have a continuous spectral kernel and a sober base space without having the open support property. An example of this is the universal quotient vector bundle with Hausdorff fibers for a locally convex space \( A \), whose base space \( \text{Max} A \) is sober — see Theorem 6.16 below.

5.11. Example. For examples with the open support property but discontinuous spectral kernel see Theorem 6.20 below, where it is also shown that for suitable \( A \) (in particular finite dimensional) we obtain spectral vector bundles whose base spaces are sober and \( T_1 \) (cf. Lemma 6.4), but not Hausdorff (cf. Example 6.5).

There is also a necessary condition for spectrality in terms of the kernel map \( \kappa \), based on Lemma 5.2:

5.12. Lemma. Let \( A = (\pi : E \to X, A, q) \) be a spectral vector bundle with kernel map \( \kappa \). For all \( x, y \in X \) we have the following implication, where \( \sqsubseteq \) denotes the specialization preorder of the topology of \( X \):

\[
x \sqsubseteq y \Rightarrow \overline{\kappa(x)} = \overline{\kappa(y)} .
\]

Proof. Let \( x, y \in X \) be such that \( x \sqsubseteq y \). Then \( \text{sob}(x) \sqsubseteq \text{sob}(y) \) in \( \Sigma(\Delta) \), which is equivalent to \( \text{sob}(y) \leq \text{sob}(x) \), and thus by Lemma 5.2 we obtain

\[
\overline{\kappa(x)} = \gamma(\text{sob}(x)) = \gamma(\text{sob}(y)) = \kappa(y) .
\]

Less obvious is that Lemma 5.2 has a converse for bundles, which gives us a necessary and sufficient condition for spectrality:

5.13. Theorem. Let \( A = (\pi : E \to X, A, q) \) be a quotient vector bundle satisfying the open support property. Then the spectral kernel \( \mathfrak{k} \) is continuous (and thus \( A \) is a spectral vector bundle) if and only if for all \( P, Q \in \Sigma \Omega(X) \) we have the implication

\[
P \subset Q \Rightarrow \overline{\mathfrak{k}(P)} = \overline{\mathfrak{k}(Q)} .
\]

(5.4)

Proof. If \( \mathfrak{k} \) is continuous we obtain (5.4) from Lemma 5.2 and Lemma 5.5, so it remains to be proved only that (5.4) implies the continuity of \( \mathfrak{k} \). In order to prove this we shall show that for any open set \( W \subset \text{Sub} A \) we have

\[
\mathfrak{k}^{-1}(W) = U_{\kappa^{-1}(W)} ,
\]

(5.5)

where \( \kappa \) is the kernel map. Let \( P \in U_{\kappa^{-1}(W)} \). Then \( \kappa^{-1}(W) \not\subset P \), so there is \( x \in X \) such that \( x \in \kappa^{-1}(W) \) and \( x \notin P \). But then \( \kappa(x) \in W \) and

\[
x \notin P \iff P \subset \text{sob}(x) \implies \mathfrak{k}(P) \equiv \mathfrak{k}(\text{sob}(x)) = \kappa(x) ,
\]
where $\equiv$ denotes topological equivalence. Since $\kappa(x) \in W$ and $\mathfrak{f}(P) \equiv \kappa(x)$ we have $\mathfrak{f}(P) \in W$, and thus $P \in \mathfrak{f}^{-1}(W)$.

Reciprocally, assume $P \in \mathfrak{f}^{-1}(W)$, that is, $\mathfrak{f}(P) \in W$. Then for any $x \notin P$ we have $P \subset \text{sob}(x)$, so

$$\kappa(x) = \mathfrak{f}(\text{sob}(x)) \equiv \mathfrak{f}(P),$$

and hence $\kappa(x) \in W$. This shows that $X \setminus P \subset \kappa^{-1}(W)$. But then, since $P \neq X$, we have $\kappa^{-1}(W) \not\subset P$, so $P \in U_{\kappa^{-1}(W)}$, and this proves (5.5).

**The spectrum of a linearized locale.** Let $\mathfrak{A} = (\triangle, A, \sigma, \gamma)$ be a linearized locale. We define its spectrum to be the quotient vector bundle

$$\Sigma(\mathfrak{A}) = \mathfrak{f}^*(UA)$$

which is classified by the continuous map

$$\mathfrak{f} = \gamma|_{\Sigma(\triangle)} : \Sigma(\triangle) \to \text{Sub } A.$$

**5.14. Lemma.** For any linearized locale $\mathfrak{A}$, the spectrum $\Sigma(\mathfrak{A})$ is a spectral vector bundle.

**Proof.** Let us use the following notation:

$$\Omega \Sigma(\mathfrak{A}) = (\Omega \Sigma(\triangle), A, \sigma, \gamma).$$

The base space of $\Sigma(\mathfrak{A})$ is $\Sigma(\triangle)$, which is a sober space, so, by Lemma 5.7 and Lemma 5.8, we need only verify that for each $a \in A$ the set

$$\{p \in \Sigma(\triangle) \mid a \notin \gamma(p)\}$$

is open in $\Sigma(\triangle)$. This follows from the adjunction $\sigma \dashv \gamma$, because for all $p \in \Sigma(\triangle)$ and $a \in A$ we have

$$\sigma(\langle a \rangle) \leq p \iff \langle a \rangle \subset \gamma(p),$$

and thus $\{p \in \Sigma(\triangle) \mid a \notin \gamma(p)\}$ is the open set $U_{\sigma(\langle a \rangle)}$.

**5.15. Theorem.** The assignment $\mathfrak{A} \mapsto \Sigma(\mathfrak{A})$ extends to a functor

$$\Sigma : \text{LinLoc} \to \text{QVBun}_\Sigma.$$

Moreover, this functor restricts to the corresponding strict categories:

$$\Sigma : \text{sLinLoc} \to \text{sQVBun}_\Sigma.$$
525

Proof. Let $\mathcal{A} = (\triangle, A, \sigma, \gamma)$ and $\mathcal{A}' = (\triangle', A', \sigma', \gamma')$ be linearized locales, and let $f = (f, \overline{f}) : \mathcal{A}' \to \mathcal{A}$ be a morphism in $\text{LinLoc}$. Defining $f^\flat = f_*\mid_{\Sigma(\triangle')} : \Sigma(\triangle') \to \Sigma(\triangle)$, we obtain a morphism $f : \Sigma(\mathcal{A}') \to \Sigma(\mathcal{A})$ in $\text{QVBun}$.

In order to see this we only need to prove that (3.6) holds. Let $a \in A$ and $y \in \Sigma(\triangle')$, and denote by $\mathcal{F}$ and $\mathcal{F}'$ the restrictions of $\gamma$ and $\gamma'$, respectively, to $\Sigma(\triangle)$ and $\Sigma(\triangle')$. Denote also the quotient vector bundles as follows:

$$\Sigma(\mathcal{A}) = (\pi : E \to \Sigma(\triangle), A, q)$$
$$\Sigma(\mathcal{A}') = (\pi' : E' \to \Sigma(\triangle'), A', q')$$

Then, for all $a \in A$ and $y \in \Sigma(\triangle')$, we have

$$q(a, f_*(y)) = 0 \iff a \in \mathcal{F}(f_*(y)) \iff a \in \gamma \circ f_* \circ \gamma'(y) \iff \overline{f}(a) \in \mathcal{F}'(y) \iff f^*(a) \in \mathcal{F}'(y) \iff q'(f^*(a), y) = 0.$$

Hence, (3.6) holds. It is also clear that if $f$ is a strict morphism then the above implication is another equivalence, and thus $f$ is also strict. The functoriality is evident, so we have obtained two functors as intended.

5.16. Adjunctions and equivalences.

A left adjoint to the spectrum functor. For each spectral vector bundle $\mathcal{A} = (\pi : E \to X, A, q)$, let

$$\Omega(\mathcal{A}) = (\Omega(X), A, \sigma, \gamma)$$

be the corresponding linearized locale.

5.17. Lemma. Let $\mathcal{A} = (\pi : E \to X, A, q)$ be a spectral vector bundle with kernel map $\kappa$, and let

$$\Sigma \Omega(\mathcal{A}) = (p : E \to \Sigma \Omega(X), A, q)$$

with kernel map $\mathcal{F}$. Then

$$\text{so}_{\mathcal{A}} := (\text{so}_{\mathcal{X}}, \text{id}_{\mathcal{A}}) : \mathcal{A} \to \Sigma \Omega(\mathcal{A})$$

is a morphism in $sQV\text{Bun}_\Sigma$. 

\]
Proof. The condition for being a strict morphism is given by (3.8), so for all \( a \in A \) and \( x \in X \) we must prove the equivalence
\[
q(a, \text{sob}_X(x)) = 0 \iff q(a, x) = 0 ,
\]
which is immediate because \( \xi(\text{sob}_X(x)) = \kappa(x) \):
\[
q(a, \text{sob}_X(x)) = 0 \iff a \in \xi(\text{sob}_X(x)) \iff a \in \kappa(x) \iff q(a, x) = 0 .
\]
Hence, since both \( A \) and \( \Sigma \Omega(A) \) are spectral (cf. Lemma 5.14), \( \text{sob}_A \) is indeed a morphism in \( sQVBun_{\Sigma} \).

5.18. Remark. Note that for \( \text{sob}_A \) to be a morphism at all it is necessary that it be strict, for the weaker condition (3.6) in this case reads
\[
q(a, \text{sob}_X(x)) = 0 = \Rightarrow q(a, x) = 0 ,
\]
which implies
\[
\xi \circ \text{sob}_X \leq \kappa
\]
and, by Lemma 5.7, is equivalent to strictness. Hence, for any quotient vector bundle \( A \) with continuous \( \xi \), the following conditions are equivalent:

1. \( A \) is spectral;
2. \( \text{sob}_A \) is a morphism;
3. \( \text{sob}_A \) is a strict morphism.

5.19. Theorem. The assignment \( A \mapsto \Omega(A) \) extends to a functor
\[
\Omega : QVBun_{\Sigma} \rightarrow \text{LinLoc} ,
\]
which is left adjoint to \( \Sigma \). Moreover the unit of the adjunction is the family \( \{ \text{sob}_A \}_A \), and the adjunction restricts to the strict subcategories \( sQVBun_{\Sigma} \) and \( s\text{LinLoc} \).

Proof. In order to prove the theorem we shall show, for an arbitrary spectral vector bundle \( A \), that \( (\Omega(A), \text{sob}_A) \) is a universal arrow from \( A \) to \( \Sigma \). So let the following be, respectively, a spectral vector bundle and a linearized locale,
\[
\mathcal{A} = (\pi : E \rightarrow X, A, q) , \quad \mathfrak{B} = (\triangle, B, \sigma_B, \gamma_B) ,
\]
and let \( f = (f_!, f^*) : A \rightarrow \Sigma(\mathfrak{B}) \) be a morphism in \( QVBun_{\Sigma} \) (cf. Lemma 5.14). We need to prove that there is a unique morphism of linearized locales
\[
\bar{f} = (\bar{f}, \bar{f}) : \Omega(A) \rightarrow \mathfrak{B}
\]
such that the following diagram commutes:

\[
\begin{array}{ccc}
A & \overset{sob_A}{\longrightarrow} & \Sigma \Omega(A) \\
\downarrow f & & \downarrow \Sigma(f) \\
\Sigma(B) & & \\
\end{array}
\]

Let us use the following notations for the structure maps of \(\Omega(A)\) and \(\Sigma(B)\):

\[
\Omega(A) = (\Omega(X), A, \sigma_A, \gamma_A),
\]

\[
\Sigma(B) = (\pi' : E' \to \Sigma(\Delta), B, q').
\]

Due to the adjunction \(\Omega \vdash \Sigma\) between \(Top\) and \(Loc\) there is in \(Loc\) a unique map \(f : \Omega(X) \to \Delta\) such that \(\Sigma(f) \circ sob_X = f^\flat\) — its inverse image is defined, for all \(d \in \Delta\), by

\[
f^*(d) = f_b^{-1}(U_d),
\]

where \(U_d = \{p \in \Sigma(\Delta) \mid d \not< p\}\). In addition, \(f\) must obviously be \(f^*\), so we must now verify that (5.1) holds for \(f\). With the necessary notation changes this condition is, for all \(V \in \text{Sub} B\),

\[
\sigma_A(f^*(V)) \subset f^* (\sigma_B(V)),
\]

or, using (5.6),

\[
\sigma_A(f^*(V)) \subset f_b^{-1}(U_{\sigma_B(V)}).
\]

In order to prove the latter condition we shall prove that, for all \(x \in X\), if \(x \not\in f_b^{-1}(U_{\sigma_B(V)})\) then \(x \not\in \sigma_A(f^*(V))\). Let then \(x \not\in f_b^{-1}(U_{\sigma_B(V)})\). This is equivalent to \(f_b(x) \not\in U_{\sigma_B(V)}\), which in turn is equivalent to \(\sigma_B(V) \leq f_b(x)\), and, by adjointness, to

\[
V \subset \gamma_B(f_b(x)).
\]

Now \(f_b(x) \in \Sigma(\Delta)\) and thus, by definition, \(\gamma_B(f_b(x)) = \kappa'(f_b(x))\), where \(\kappa'\) is the kernel map of \(\Sigma(B)\). Hence, (5.9) is equivalent to the statement that every \(a \in V\) satisfies \(a \in \kappa'(f_b(x))\), which in turn is equivalent to

\[
\forall a \in V \ q'(a, f_b(x)) = 0.
\]

Since \(f\) is a morphism of quotient vector bundles the latter implies

\[
\forall a \in V \ q(f^*(a), x) = 0,
\]

which is equivalent to

\[
f^*(V) \subset \kappa(x).
\]

Since \(A\) is spectral we have \(\kappa = t \circ sob_X\), and thus (5.12) is equivalent to

\[
f^*(V) \subset t(sob_X(x)) = \gamma_A(sob_X(x)).
\]
and, by adjointness, equivalent to
\[
\sigma_A(f^*(V)) \subset \text{sob}_X(x) = X \setminus \{x\},
\]
which, since \(\sigma_A(f^*(V))\) is open in \(X\), is equivalent to
\[
x \notin \sigma_A(f^*(V)).
\] (5.13)

This concludes the proof of the inclusion (5.8), and establishes the adjunction \(\Omega \vdash \Sigma\).

Now we note that all but one of the steps in the above proof of (5.7) are equivalences. But if \(f\) is a strict morphism the implication (5.10) \(\Rightarrow\) (5.11) becomes an equivalence, too, and we obtain
\[
\sigma_A(f^*(V)) = f^*(\sigma_B(V)) ,
\]
which means that \(f\) is strict. Together with the fact that \(\text{sob}_A\) is strict, this proves that the adjunction restricts to the strict subcategories.

**Sober vector bundles.** Let \(\mathcal{A} = (\pi : E \to X, A, q)\) be a quotient vector bundle with kernel map \(\kappa : X \to \text{Sub} A\). We say that \(\mathcal{A}\) is a **sober vector bundle** if the two following conditions hold:

- \(X\) is a sober space;
- \(\mathcal{A}\) has the open support property.

By Lemma 5.7 and Lemma 5.8 we immediately obtain:

**5.20. Corollary.** The following conditions satisfy \((1) \Rightarrow (2) \Rightarrow (3)\):
1. \(X\) is sober and the zero-section of \(\mathcal{A}\) is closed in \(E\);
2. \(\mathcal{A}\) is sober;
3. \(\mathcal{A}\) is spectral.

**5.21. Example.** Any Banach bundle on a locally compact Hausdorff space can be made a sober vector bundle (cf. Example 5.9). Examples of quotient vector bundles that are spectral but not sober can of course be obtained from any sober vector bundle \((\pi : E \to X, A, q)\) by pulling it back along a quotient map \(Y \to X\) such that \(Y\) is not sober.

**5.22. Theorem.** Let \(\mathfrak{A} = (\Delta, A, \sigma, \gamma)\) and \(\mathcal{A} = (\pi, A, q)\) be a linearized locale and a quotient vector bundle, respectively.

1. The spectrum \(\Sigma(\mathfrak{A})\) is a sober vector bundle.
2. The bundle \(\mathcal{A}\) is sober if and only if
\[
\text{sob}_\mathcal{A} = (\text{sob}_X, \text{id}_A) : \mathcal{A} \to \Sigma \Omega(\mathcal{A})
\]
is an isomorphism.

**Proof.** We have already seen in Lemma 5.14 that \(\Sigma(\mathfrak{A})\) is spectral, so it is sober because \(\Sigma(\Delta)\) is. This proves (1), and (2) is obvious. \(\blacksquare\)
Spatial linearized locales. Let $\mathfrak{A} = (\triangle, A, \sigma, \gamma)$ be a linearized locale. The spatialization of $\mathfrak{A}$ is the pair

$$\text{spat}_{\mathfrak{A}} = (\text{spat}_\triangle: \Omega \Sigma(\triangle) \to \triangle, \text{id}_A: A \to A).$$

5.23. Theorem. $\text{spat}_{\mathfrak{A}}$ is a strict morphism of linearized locales $\Omega \Sigma(\mathfrak{A}) \to \mathfrak{A}$.

Proof. Let $\Omega \Sigma(\mathfrak{A}) = (\Omega \Sigma(\triangle), A, \check{\sigma}, \check{\gamma})$. Then $\text{spat}_{\mathfrak{A}}$ is a strict morphism if and only if the following square commutes:

```
Sub A  ↓ id_A  ↓
| σ     | σ
△ ----> Sub A ----> △
| spat_△ | spat_△
Ω Σ(△) ----> Ω Σ(△)
```

Let $V \in \text{Sub} A$. We have

$$\check{\sigma}(V) = \bigcup_{a \in V} \text{int}\{p \in \Sigma(\triangle) \mid a \notin \gamma(p)\}$$

$$= \bigcup_{a \in V} \{p \in \Sigma(\triangle) \mid a \notin \gamma(p)\} \quad \text{(by Lemma 5.7 and Lemma 5.14)}$$

$$= \bigcup_{a \in V} \{p \in \Sigma(\triangle) \mid \sigma(\langle a \rangle) \notin p\} \quad \text{(because } \sigma \dashv \gamma\text{)}$$

$$= \bigcup_{a \in V} U_{\sigma(\langle a \rangle)} = U_{\sigma(V)} = \text{spat}_\triangle^*(\sigma(V)),$$

and thus we have $\check{\sigma} = \text{spat}_\triangle^* \circ \sigma$, as intended.

We say that $\mathfrak{A}$ is spatial if $\triangle$ is a spatial locale. This is equivalent to stating that $\text{spat}_{\mathfrak{A}}$ is an isomorphism of linearized locales. It immediately follows that the adjunction $\Omega \dashv \Sigma$ restricts to another adjunction, between the full subcategories of sober vector bundles and spatial linearized locales, whose unit and co-unit are isomorphisms. Hence, we are provided with a linearized version of the equivalence of categories between sober spaces and spatial locales:

5.24. Corollary. The adjunction $\Omega \dashv \Sigma$ restricts to an equivalence between the full subcategories of $QVBun_\Sigma$ and $\text{LinLoc}$ whose objects are, respectively, the sober vector bundles and the spatial linearized locales. This further restricts to an equivalence between the respective subcategories whose morphisms are strict.

5.25. Bundles with Hausdorff fibers.
Max-valued linear structures. A quotient vector bundle $(\pi, A, q)$ has Hausdorff fibers if and only if its kernel map is valued in $\text{Max } A$. All our previous results carry through to this setting, and we briefly examine this.

First, we notice that $\text{Max } A$ is both a topological retract of $\text{Sub } A$ (under the lower Vietoris topology) and a quotient sup-lattice given by the topological closure operator. In other words, we have an adjunction

\[
\begin{array}{ccc}
\text{Sub } A & \xrightarrow{\perp} & \text{Max } A \\
\iota \downarrow & \downarrow & \iota \\
\end{array}
\]

where both the inclusion $\iota$ and the surjection $(-)$ are continuous.

Now let $\mathfrak{A} = (\Delta, A, \sigma, \gamma)$ be a linearized locale. Then $\gamma$ is valued in $\text{Max } A$ if and only if $\sigma$ factors through $\text{Max } A$ — that is, $\sigma(V) = \sigma(\overline{V})$ for all $V \in \text{Sub } A$ —, in which case we obtain an adjunction

\[
\begin{array}{ccc}
\text{Max } A & \xrightarrow{\sigma|_{\text{Max } A}} & \Delta \\
\gamma \downarrow & \downarrow & \gamma \\
\end{array}
\]

and the kernel map $\kappa$ is continuous as a map to $\text{Max } A$.

Conversely, given an adjunction

\[
\begin{array}{ccc}
\text{Max } A & \xrightarrow{\sigma} & \Delta \\
\gamma \downarrow & \downarrow & \gamma \\
\end{array}
\]

such that $\kappa := \gamma|_{\Sigma(\Delta)} : \Sigma(\Delta) \to \text{Max } A$ is continuous, composing this with the adjunction of (5.14) we obtain a linearized locale $((\Delta, A, (-) \circ \sigma, \iota \circ \gamma))$, whose kernel map is $\iota \circ \kappa$.

Let us refer to such a linearized locale as a Max-linearized locale. All our results in section 5 remain true if restricted to Max-linearized locales and spectral vector bundles with Hausdorff fibers. In addition we note that, by Lemma 5.2, if $(\Delta, A, \sigma, \gamma)$ is a Max-linearized locale then for all $p, q \in \Sigma(\Delta)$ we have the following implication:

\[
p \leq q \Rightarrow \gamma(p) = \gamma(q).
\]

Spectral vector bundles revisited. Lemma 5.12 has the following simple consequences:

5.26. Corollary. Let $\mathfrak{A} = (\pi : E \to X, A, q)$ be a spectral vector bundle with Hausdorff fibers and kernel map $\kappa$. For all $x, y \in X$ we have the following implication, where $\sqsubseteq$ denotes the specialization preorder of the topology of $X$:

\[
x \sqsubseteq y \Rightarrow \kappa(x) = \kappa(y).
\]

5.27. Corollary. Spectral vector bundles with Hausdorff fibers and injective kernel maps must have $T_1$ base spaces.

We also rewrite Theorem 5.13 for bundles with Hausdorff fibers:
5.28. Corollary. Let $\mathcal{A} = (\pi : E \to X, A, q)$ be a quotient vector bundle with Hausdorff fibers satisfying the open support property. Then the spectral kernel $\mathfrak{k}$ is continuous (and thus $\mathcal{A}$ is a spectral vector bundle) if and only if for all $P, Q \in \Sigma \Omega(X)$ we have the implication

$$P \subset Q \Rightarrow \mathfrak{k}(P) = \mathfrak{k}(Q).$$

(5.17)

6. Classifying spaces and universal bundles

In this section we define the open support topology on the spectrum $\text{Sub} A$ of an arbitrary topological vector space $A$. This topology is finer than the lower Vietoris topology (for instance $\text{Max} A$ becomes a $T_1$ space) but in general coarser than the Fell topology. We write $\text{Sub}^o A$ for $\text{Sub} A$ with the open support topology. This space classifies the spectral vector bundles, at least those over base spaces $X$ such that $\text{sob}_X$ is surjective (e.g., Hausdorff spaces). We also show that this classification does not necessarily apply to more general spaces $X$ because although the quotient vector bundles classified by continuous maps $\kappa : X \to \text{Sub} A$ have the open support property, their spectral kernels may fail to be continuous. In particular, in general there is no universal spectral vector bundle for a given topological vector space $A$. Conversely, we prove, for any locally convex space $A$, that the quotient vector bundle determined by the inclusion $\text{Max} A \to \text{Sub} A$ (with the lower Vietoris topology) does not have the open support property but that its spectral kernel is continuous (in fact constant). Along the way we obtain general results concerning the prime open sets of topologies on $\text{Sub} A$ that are finer than the lower Vietoris topology, in particular concluding that for locally convex spaces $A$ the space $\text{Max} A$ is sober.

Open support topology. Let $A$ be a topological vector space. For each $a \in A$ let

$$\check{a} = \{ P \in \text{Sub} A \mid a \notin P \}.$$ 

The coarsest topology on $\text{Sub} A$ that contains the lower Vietoris topology and makes all the sets $\check{a}$ open will be referred to as the open support topology. The terminology is motivated by the following lemma:

6.2. Lemma. Let $\mathcal{A}$ be a quotient vector bundle. Then $\mathcal{A}$ has the open support property if and only if its kernel map is continuous with respect to the open support topology.

Proof. Let $\kappa$ be the kernel map of $\mathcal{A}$. Continuity of $\kappa$ with respect to the open support topology is, since $\kappa$ is continuous with respect to the lower Vietoris topology (because it is a kernel map), just the statement that for all $a \in A$ the set $\kappa^{-1}(\check{a})$ is open. But, by Lemma 5.7, this is equivalent to the open support property because $\kappa^{-1}(\check{a}) = \{ x \in X \mid a \notin \kappa(x) \}$. 

\hfill \blacksquare
We shall denote by $\text{Sub}^\circ A$ and $\text{Max}^\circ A$ the spaces $\text{Sub} A$ and $\text{Max} A$ equipped with the open support topology.

6.3. Corollary. Let $X$ be a topological space whose soberification map $\text{sob} : X \to \Sigma \Omega (X)$ is surjective. Then the spectral vector bundles $(\pi, A, q)$ are, up to isomorphism, in bijective correspondence with the continuous maps $\kappa : X \to \text{Sub}^\circ A$. This applies in particular to all sober spaces $X$, and thus also to Hausdorff spaces.

We note the following property, which will be used later on:

6.4. Lemma. $\text{Max}^\circ A$ is a $T_1$ space.

Proof. Let $V, W \in \text{Max}^\circ A$ be distinct elements. Without loss of generality assume that $V \not\subset W$, and let $a \in V \setminus W$. Then we have both $W \in \check{a}$ and $V \not\in \check{a}$, on one hand, and, on the other, $W \not\in \sim A \setminus W$ and $V \in \sim A \setminus W$. ■

Note, however, that $\text{Max}^\circ A$ is never a Hausdorff space if $\dim A \geq 2$. The following example illustrates this:

6.5. Example. Each open set of $\text{Max}^\circ \mathbb{C}^2$ is an open set of the lower Vietoris topology minus a finite number of rays. This implies that $\{(0, 0)\}$ and $\langle (z, w) \rangle$ cannot be separated by disjoint neighborhoods if $(z, w) \neq (0, 0)$, since any basic open neighborhood of $\langle (z, w) \rangle$ is generated by an open set of the Grassmannian $\mathbf{Gr}(1, \mathbb{C}^2)$ (see [22, Th. 7.5]).

Fell topology. The open support topology is defined in a similar way to the Fell topology [7] (see also [16, 22]), but the latter has subbasic open sets

$$\check{K} = \{ V \in \text{Max} A \mid V \cap K = \emptyset \}$$

for each compact subset $K \subset A$ instead of only $\check{a} = \{ \check{a} \}$ for $a \in A$. Therefore the Fell topology is obviously finer than the open support topology. Next we show that under mild restrictions it is strictly finer.

6.6. Lemma. Let $A$ be a first countable topological vector space such that $\dim A > 2$. Then there is a compact set $K \subset A$ which is not contained in any finite union of 2-dimensional subspaces.

Proof. Let $e_0 \in A$ and let $\{ U_n \}$ be a countable basis of neighborhoods of $e_0$ with $U_{n+1} \subset U_n$ for all $n$. There is a sequence $(e_n)$ in $A$ such that $e_n \in U_n$ for all $n$, with the property that for any $i < j < k$ the vectors $e_i, e_j, e_k$ are linearly independent: assume we have chosen $e_1, \ldots, e_{n-1}$ such that the list $e_0, \ldots, e_{n-1}$ has this property, and let $C = \bigcup_{i<j<n} \langle e_i, e_j \rangle$; since $A \setminus C$ is open and dense, we can choose $e_n \in U_n \cap (A \setminus C)$, and the list $e_0, \ldots, e_n$ has the required property. Now let $K = \{ e_n \}_{n \geq 0}$. The set $K$ is compact and no 2-dimensional subspace contains more than two elements of $K$. ■
6.7. **Theorem.** Let $A$ be a first countable topological vector space such that $\dim A > 2$. Then the open support topology is strictly coarser than the Fell topology.

**Proof.** Let $K \subset A$ be a compact set which is not contained in any finite union of 2-dimensional subspaces (cf. Lemma 6.6). The set $\hat{K} = \{ V \in \text{Max} A \mid V \cap K = \emptyset \}$ is open in the Fell topology. Let $a \in A$ be such that $\langle a \rangle \in \hat{K}$. We will show that no neighborhood of $\langle a \rangle$ in the open support topology is contained in $\hat{K}$. Any basic neighborhood of $\langle a \rangle$ in the open support topology is of the form $U \cap \mathring{c}_1 \cap \cdots \cap \mathring{c}_n$ with $U \subset \text{Max} A$ open in the lower Vietoris topology and $c_1, \ldots, c_n \notin \langle a \rangle$. But then $\langle a, b \rangle \in U$ for any $b \in A$. Let $C = \bigcup_i \langle a, c_i \rangle$ and choose $b \in K \setminus C$. Then for any $i$ we have $b \notin \langle a, c_i \rangle$, so $c_i \notin \langle a, b \rangle$ because $c_i \notin \langle a \rangle$. It follows that $\langle a, b \rangle \in U \cap \mathring{c}_1 \cap \cdots \cap \mathring{c}_n$. But $\langle a, b \rangle \notin \hat{K}$, so $\hat{K}$ is not open in the open support topology.

6.8. **Grassmannians.**

**The Grassmannian of a Hausdorff vector space.** Let $A$ be a Hausdorff vector space. Recall [22] that the $k$-**Grassmannian** of $A$ is the set $\text{Gr}(k, A)$ of $k$-dimensional linear subspaces of $A$, carrying the quotient topology given by the identification $\text{Gr}(k, A) \cong V(k, A)/\text{GL}(k, \mathbb{C})$, where $V(k, A)$ is the space of injective linear maps from $\mathbb{C}^k$ to $A$ with the product topology. Hence, the surjection $V(k, A) \to \text{Gr}(k, A)$ that is defined by $\phi \mapsto \text{Im} \phi$ is a continuous open map.

We have $\text{Gr}(k, A) \subset \text{Max} A$ because finite dimensional subspaces of a Hausdorff vector space are closed, and in [22, Th. 7.2] it is shown that $\text{Gr}(k, A)$ is a topological subspace of $\text{Max} A$ with the lower Vietoris topology. In addition, below we shall use the fact [22, Th. 7.5] that a basis of the lower Vietoris topology of $\text{Max} A$ consists of all the sets of the form

$$\uparrow \mathcal{C} := \{ V \in \text{Max} A \mid \exists W \in \mathcal{C} \ W \subset V \},$$

where $\mathcal{C}$ is an open set of a Grassmannian $\text{Gr}(k, A)$ for some $k \in \mathbb{N}_{>0}$.

**Spaces of linear maps.** Write $L(k, A)$ for the space of all the linear maps from $\mathbb{C}^k$ to $A$ with the product topology. We note that we have a homeomorphism $L(k, A) \cong A^k$, under which $V(k, A)$ can be identified with the subspace of linearly independent $k$-tuples.

6.9. **Lemma.** Let $A$ be a topological vector space. Any proper linear subspace $V \subset A$ has empty interior.

**Proof.** Let $V \subset A$ be a proper linear subspace. For all $U \subset V$, $v \in U$, and $w \notin V$, let $f: \mathbb{C} \to A$ be the map defined by $f(\lambda) = v + \lambda w$. Then for all $\lambda \neq 0$ we have $f(\lambda) \notin V$, and thus $f^{-1}(U) = \{0\}$, showing that $U$ cannot be open.

6.10. **Lemma.** Let $A$ be a Hausdorff vector space. If $\dim A \geq k$ then $V(k, A)$ is dense and open in $L(k, A)$.
Proof. We identify $L(k, A)$ with $A^k$. Let us prove density. Let $U = U_1 \times \cdots \times U_k \subset A^k$ with each $U_i$ open in $A$, and let $a = (a_1, \ldots, a_k) \in U$ be such that $d = \dim \langle a_1, \ldots, a_k \rangle$ is maximal. Assume that $d < k$. Then $\langle a_1, \ldots, a_k \rangle$ is a proper subspace of $A$, hence by Lemma 6.9 with empty interior. Without loss of generality, assuming that $d < k$ is maximal. Assume that $U$ with each $a, b, c \in U$ is independent if for all permutations $p$ of $\{1, 2, 3\}$ we have $V_p(1) \cap (V_p(2) + V_p(3)) = \{0\}$. Equivalently, the mapping $(a, b, c) \mapsto a + b + c$ defines an isomorphism $V_1 \oplus V_2 \oplus V_3 \cong V_1 + V_2 + V_3$.

6.11. Lemma. Let $A$ be a Hausdorff vector space, $V \in \text{Max } A$, and $k_1, k_2 \in \mathbb{N}_{>0}$.

1. If $\text{codim } V \geq k_1 + k_2$ then the subspace of pairs $(W_1, W_2)$ such that $V, W_1$ and $W_2$ are independent is open in $\text{Gr}(k_1, A) \times \text{Gr}(k_2, A)$.

2. Let $a \notin V$. If $\text{codim } V \geq k_1 + k_2 + 1$ then the subset

$$W_a = \{(W_1, W_2) \mid a \notin V + W_1 + W_2 \text{ and } V, W_1, W_2 \text{ are independent}\}$$

is open and dense in $\text{Gr}(k_1, A) \times \text{Gr}(k_2, A)$.

3. Let $a = (a_1, \ldots, a_m) \in (A \setminus V)^m$. If $\text{codim } V \geq k_1 + k_2 + 1$ then the subset

$$W_a = \{(W_1, W_2) \mid a_1, \ldots, a_m \notin V + W_1 + W_2 \text{ and } V, W_1, W_2 \text{ are independent}\}$$

is open and dense in $\text{Gr}(k_1, A) \times \text{Gr}(k_2, A)$.

4. Let $a = (a_1, \ldots, a_m) \in (A \setminus V)^m$. If $\text{codim } V \geq k_1 + k_2 + 1$ then the subset

$$X_a = \{(W_1, W_2) \mid a_1, \ldots, a_m \notin V + W_1 + W_2\}$$

is dense in $\text{Gr}(k_1, A) \times \text{Gr}(k_2, A)$.

Proof. Let $k = k_1 + k_2$. The quotient space $A/V$ is Hausdorff because $V$ is closed, and, since we have $\dim A/V \geq k$, by Lemma 6.10 we conclude that $V(k, A/V)$ is open in $L(k, A/V)$. Hence, $\psi^{-1}(V(k, A/V))$ is open in $L(k_1, A) \times L(k_2, A)$, where $\psi$ is given by the following composition:

$$L(k_1, A) \times L(k_2, A) \xrightarrow{\cong} L(k, A) \xrightarrow{\psi} L(k, A/V)$$
[Under the identification provided by the isomorphism $L(k, A) \cong A^k$, the map $\psi$ is the $k$-fold quotient map $A^k \to (A/V)^k$.] Moreover, in fact we have $\psi^{-1}(V(k, A/V)) \subset V(k_1, A) \times V(k_2, A)$, and furthermore $\psi^{-1}(V(k, A/V))$ is the subspace of pairs $(\phi_1, \phi_2)$ such that the spaces $V$, Im $\phi_1$ and Im $\phi_2$ are independent. Hence, since the quotient map $V(k, A) \to Gr(k, A)$ is open, the subspace of pairs $(W_1, W_2) \in Gr(k_1, A) \times Gr(k_2, A)$ such that $V, W_1$ and $W_2$ are independent is open in $Gr(k_1, A) \times Gr(k_2, A)$. This proves (1).

In order to prove (2), assume $a \notin V$ and codim $V \geq k + 1$, and let $V_a = V \oplus \langle a \rangle$. Then dim $A/V_a \geq k$ and, again by Lemma 6.10, $V(k, A/V_a)$ is dense in $L(k, A/V_a)$. Since $\psi$ is open and surjective, $\psi^{-1}(V(k, A/V_a)) \subset V(k_1, A) \times V(k_2, A)$ is also dense. Now $\psi^{-1}(V(k, A/V_a))$ is the subspace of pairs $(\phi_1, \phi_2) \in V(k_1, A) \times V(k_2, A)$ such that the spaces $V_a$, Im $\phi_1$ and Im $\phi_2$ are independent. Such pairs are precisely the elements of the subspace

$$\{(\phi_1, \phi_2) \mid a \notin V + \text{Im } \phi_1 + \text{Im } \phi_2 \quad \text{and} \quad V, \text{Im } \phi_1, \text{Im } \phi_2 \text{ are independent}\},$$

which therefore is open and dense in $V(k_1, A) \times V(k_2, A)$. Hence, applying the quotient $\phi_i \mapsto \text{Im } \phi_i$ we conclude that $W_a$ is dense in $Gr(k_1, A) \times Gr(k_2, A)$, thus proving (2).

Now let us prove (3). For each $i$ we have $a_i \notin V$, by (2) the set $W_{a_i}$ is open and dense in $Gr(k_1, A) \times Gr(k_2, A)$, and thus so is the finite intersection $W_a = W_{a_1} \cap \ldots \cap W_{a_m}$.

Finally, (4) follows from (3) because $W_a \subset X_a$.

**Lower Vietoris topology revisited.** In general it is not true, given some topological vector space $A$, that $U_1 \cap U_2 = \tilde{U}_1 \cap \tilde{U}_2$ for arbitrary open sets $U_1, U_2 \subset A$. The following lemma provides an example where this equality holds, involving convex open sets.

6.13. **Lemma.** Let $A$ be a topological vector space, let $U \subset A$ be a convex open set, and let $a \in A$. Let

$$U^+ = \bigcup_{\lambda \geq 0}(U + \lambda a) \quad \text{and} \quad U^- = \bigcup_{\lambda \geq 0}(U - \lambda a).$$

Then $\tilde{U}^+ \cap \tilde{U}^- = \tilde{U}$.

**Proof.** We have $U^+ \cap U^- = U$ so $\tilde{U} \subset \tilde{U}^+ \cap \tilde{U}^-$. Let $V \in \tilde{U}^+ \cap \tilde{U}^-$ and pick $c^+ \in V \cap U^+$ and $c^- \in V \cap U^-$. Then there are $b^-, b^+ \in U$ and $\lambda^-, \lambda^+ \geq 0$ such that $c^- = b^- - \lambda^- a$ and $c^+ = b^+ + \lambda^+ a$. If $\lambda^+ = 0$ then $c^+ = b^+ \in V \cap U$ and thus $V \in \tilde{U}$. If $\lambda^+ \neq 0$ let $\mu = \lambda^- / (\lambda^+ + \lambda^-) \in [0, 1]$. Then $\mu c^+ + (1 - \mu)c^- = \mu b^+ + (1 - \mu)b^- \in V \cap U$ since both $U$ and $V$ are convex, so $V \in \tilde{U}$.
Finer topologies and their prime open sets. Given \( V_1, V_2 \in \text{Max } A \) with \( V_1 \subset V_2 \), we introduce the following notation:

\[
U_{V_1, V_2} = \text{Max } A \setminus \{ V \in \text{Max } A \mid V_1 \subset V \subset V_2 \}.
\]

Given a collection \( S \) of subsets of \( \text{Max } A \) we shall write \( \text{Max}^S A \) for \( \text{Max } A \) equipped with the topology which is generated by the lower Vietorios topology and by \( S \). We state the following lemma in more generality than needed in the rest of this paper.

6.14. Lemma. Let \( A \) be a locally convex space, let \( S \) be a collection of subsets of \( \text{Max } A \), and let \( \mathcal{Y} \subset \text{Max}^S A \) be a subspace. Then for every prime open set \( \mathcal{P} \) in \( \mathcal{Y} \) there is \( V \in \text{Max } A \) such that for some union \( S \) of elements of \( S \) we have

\[
\mathcal{P} = (U_{0, V} \cup S) \cap \mathcal{Y}.
\]

Proof. Let \( \mathcal{P} \in \Sigma \Omega(\mathcal{Y}) \). Since every prime open set is the union of subbasic open sets (cf. Lemma 4.4) and for all families \( (U_a) \) of open sets of \( A \) we have \( \bigcup_a U_a = \bigcup_a \tilde{U}_a \), there is \( U \in \Omega(A) \) such that \( \mathcal{P} = (U \cup S) \cap \mathcal{Y} \), where \( S \) is a union of elements of \( S \). Let \( U_{\text{max}} \) be the union of all the open sets \( U_a \in \Omega(A) \) such that \( (U_a \cup S) \cap \mathcal{Y} = \mathcal{P} \). Then

\[
(U_{\text{max}} \cup S) \cap \mathcal{Y} = \bigcup_{\alpha} (U_{\alpha} \cup S) \cap \mathcal{Y} = \mathcal{P}.
\]

Let \( V = A \setminus U_{\text{max}} \). To complete the proof we only need to show that \( V \in \text{Max } A \), since then \( \tilde{U}_{\text{max}} = A \setminus V = U_{0, \mathcal{Y}} \).

1. First we show that if \( \lambda \in \mathbb{C} \) and \( a \in V \) then \( \lambda a \in V \). The case \( \lambda = 0 \) follows since \( 0 \notin U_{\text{max}} \), for otherwise we would have \( \tilde{U}_{\text{max}} = \text{Max } A \) and \( \mathcal{P} = \mathcal{Y} \), which is a contradiction because \( \mathcal{P} \) is prime. So assume \( \lambda \neq 0 \). Then for any open set \( U \in \Omega(A) \) we have \( \lambda U = U \) and hence, by maximality, \( \lambda U_{\text{max}} = U_{\text{max}} \). The result immediately follows.

2. Now we want to show that \( a, b \in V \Rightarrow a + b \in V \). We will prove this by contradiction. If \( a + b \in U_{\text{max}} \) then, by (1), we have \( \frac{1}{2}(a + b) \in U_{\text{max}} \), so there is a convex open set \( N \subset A \) satisfying \( \frac{1}{2}(a + b) \in N \subset U_{\text{max}} \). Let

\[
N_a = \bigcup_{\lambda \geq 0} (N + \lambda(a - b)) \quad \text{and} \quad N_b = \bigcup_{\lambda \geq 0} (N + \lambda(b - a)).
\]

Then \( a \in N_a \) and \( b \in N_b \), and, by Lemma 6.13, we have

\[
(\widetilde{N}_a \cap \mathcal{Y}) \cap (\widetilde{N}_b \cap \mathcal{Y}) = \widetilde{N} \cap \mathcal{Y} \subset \tilde{U}_{\text{max}} \cap \mathcal{Y} \subset \mathcal{P}.
\]

Hence, since \( \mathcal{P} \) is prime, we must have either \( \widetilde{N}_a \cap \mathcal{Y} \subset \mathcal{P} \) or \( \widetilde{N}_b \cap \mathcal{Y} \subset \mathcal{P} \). Without loss of generality assume that \( \widetilde{N}_a \cap \mathcal{Y} \subset \mathcal{P} \). Then

\[
((N_a \cup U_{\text{max}}) \cup S) \cap \mathcal{Y} = (\widetilde{N}_a \cup \tilde{U}_{\text{max}} \cup S) \cap \mathcal{Y} = (\widetilde{N}_a \cap \mathcal{Y}) \cup \mathcal{P} = \mathcal{P},
\]

and it follows that \( N_a \subset U_{\text{max}} \), and thus \( a \in U_{\text{max}} \). \( \blacksquare \)
6.15. **Universal bundles.**

**Universal quotient vector bundles.** We shall denote by $U^1 A$ the universal bundle with Hausdorff fibers for $A$ (which is classified by the inclusion $\text{Max } A \to \text{Sub } A$). The following result shows that the open support property may fail even for bundles with Hausdorff fibers.

6.16. **Theorem.** Let $A$ be a locally convex space. The following conditions hold:

1. $\text{Max } A$ is sober;

2. $U^1 A$ has continuous spectral kernel but it is not spectral because it does not satisfy the open support property.

**Proof.** Let $\mathcal{Y} = \text{Max } A$ and let $\mathcal{S} = \emptyset$. Then Lemma 6.14 tells us that any prime open set is of the form $\mathcal{P} = U_{\mathcal{O}} V = \text{sub}(V)$ with $V \in \text{Max } A$, and it follows that the soberification map of $\text{Max } A$ is surjective. It is also injective because $\text{Max } A$ is $T_0$, and therefore $\text{Max } A$ is sober. Now we claim that, for any $a \in A$, we have $\text{supp}^\circ \hat{a} = \emptyset$.

Suppose we have $V \in \text{supp}^\circ \hat{a}$. Then $\hat{a}(V) \neq 0$, which is equivalent to $a \notin V$. Then, since open sets of $\text{Max } A$ are upper closed we must also have $V \oplus \langle a \rangle \in \text{supp}^\circ a$, which implies $a \notin V \oplus \langle a \rangle$, a contradiction. This proves the claim, and it immediately follows that the universal bundle $U^1 A$ does not have the open support property. But its spectral kernel $\mathfrak{t}$ is continuous because it is constant, since for all $\mathcal{P} \in \Sigma \Omega(\text{Max } A)$ we have $\mathfrak{t}(\mathcal{P}) = \{a \in A \mid \text{supp}^\circ \hat{a} \subset \mathcal{P}\} = A$. 

**Prime open sets for the open support topology.** Now we use the description of prime open sets of Lemma 6.14 in order to obtain a full characterization of the prime open sets for the open support topology.

6.17. **Lemma.** Let $A$ be a topological vector space. Let also $V_1, V_2 \in \text{Max } A$ with $V_1 \subset V_2$, let $\mathcal{C} \subset \text{Max } A$, and let $a_1, \ldots, a_k \in A$. The following conditions are equivalent:

1. $\uparrow \mathcal{C} \cap \hat{a}_1 \cap \cdots \cap \hat{a}_k \not\subset U_{V_1, V_2}$;

2. There is $W \in \mathcal{C}$ such that $W \subset V_2$ and $a_1, \ldots, a_k \notin W + V_1$.

**Proof.** If $\uparrow \mathcal{C} \cap \hat{a}_1 \cap \cdots \cap \hat{a}_k \not\subset U_{V_1, V_2}$ then there is $V \in \text{Max } A$ and $W \in \mathcal{C}$ such that $W \subset V$, $a_1, \ldots, a_k \notin V$ and $V_1 \subset V \subset V_2$. It follows that $W \subset V_2$ and $a_1, \ldots, a_k \notin W + V_1$. Conversely, if there is $W \in \mathcal{C}$ such that $W \subset V_2$ and $a_1, \ldots, a_k \notin W + V_1$ then $W + V_1 \in \uparrow \mathcal{C} \cap \hat{a}_1 \cap \cdots \cap \hat{a}_k$ and $W + V_1 \notin U_{V_1, V_2}$.

6.18. **Lemma.** Let $A$ be a Hausdorff vector space, and let $V_1, V_2 \in \text{Max}^\circ A$ be such that $V_1 \subset V_2$ and the codimension of $V_1$ inside $V_2$ is infinite. Then $U_{V_1, V_2}$ is a prime open set.
Proof. Let $U_1$ and $U_2$ be open sets of $\text{Max}^0 A$. We shall prove that $U_{V_1,V_2}$ is prime by showing that if $U_1 \not\subset U_{V_1,V_2}$ and $U_2 \not\subset U_{V_1,V_2}$ then $U_1 \cap U_2 \not\subset U_{V_1,V_2}$. Assume then that

$$U_1 \not\subset U_{V_1,V_2} \quad \text{and} \quad U_2 \not\subset U_{V_1,V_2}. \quad (6.1)$$

We may also assume that $U_1$ and $U_2$ are basic open sets, so, again by [22, Th. 7.5], we can write them in the form

$$U_1 = \uparrow C_1 \cap \tilde{a}_1 \cap \cdots \cap \tilde{a}_k \quad \text{and} \quad U_2 = \uparrow C_2 \cap \tilde{b}_1 \cap \cdots \cap \tilde{b}_n,$$

where $C_1 \subset \text{Gr}(d_1, A)$ and $C_2 \subset \text{Gr}(d_2, A)$ are open sets of Grassmannians. Then (6.1) implies, by Lemma 6.17, that $a_1, \ldots, a_k, b_1, \ldots, b_n \not\in V_1$. Since the codimension of $V_1$ in $V_2$ is infinite, we can apply Lemma 6.11(4) in order to conclude that the set

$$\{(W_1, W_2) \in \text{Gr}(d_1, V_2) \times \text{Gr}(d_2, V_2) \mid a_1, \ldots, a_k, b_1, \ldots, b_n \not\in V_1 + W_1 + W_2\}$$

is dense in $\text{Gr}(d_1, V_2) \times \text{Gr}(d_2, V_2)$ (notice that these are Grassmannians of $V_2$ rather than $A$). Condition (6.1) implies that both $U_1 \cap \text{Gr}(d_1, V_2)$ and $U_2 \cap \text{Gr}(d_2, V_2)$ are not empty, so due to density there exist $W_1 \in U_1$ and $W_2 \in U_2$ such that $W_1 + W_2 \subset V_2$ and $a_1, \ldots, a_k, b_1, \ldots, b_n \not\in V_1 + W_1 + W_2$. Finally, again by Lemma 6.17, we have

$$U_1 \cap U_2 = \uparrow (C_1 + C_2) \cap \tilde{a}_1 \cap \cdots \cap \tilde{a}_k \cap \tilde{b}_1 \cap \cdots \cap \tilde{b}_n \not\subset U_{V_1,V_2}. \quad \square$$

### 6.19. Theorem

Let $A$ be a Hausdorff locally convex space, and let $P$ be a subset of $\text{Max}^0 A$. Then $P$ is a prime open set if and only if either $P = \text{so}(V)$ for some $V \in \text{Max}^0 A$, or $P = U_{V_1,V_2}$ for some $V_1, V_2 \in \text{Max}^0 A$ such that $V_1 \subset V_2$ and the codimension of $V_1$ inside $V_2$ is infinite.

Proof. Applying Lemma 6.14 with $S = \{\tilde{a}\}_{a \in A}$ and $Y = \text{Max}^0 A = \text{Max}^0 A$, we see that $P = U_{0,V_2} \cup S$ with $V_2 \in \text{Max}^0 A$ and $S$ a union of elements of $S$. Then there is a subset $C \subset A$ such that $S = \bigcup_{c \in C} \tilde{a} = \text{cl}V_1 \subset A$, where $V_1 = \text{span} C$. Then $P = U_{0,V_2} \cup U_{V_1,A}$, and, since $P \neq Y$ because $P$ is prime, we must have $V_1 \subset V_2$, and thus $P = U_{V_1,V_2}$. If $V_1 = V_2$ then $P = \emptyset \setminus \{V_1\}$, and this equals $\text{so}(V_1)$ because, by Lemma 6.4, $\text{Max}^0 A$ is $T_1$. So let us assume $V_1 \neq V_2$. Suppose that the codimension $d$ of $V_1$ inside $V_2$ is finite. If $d = 1$ then $U_{V_1,V_2} = Y \setminus \{V_1, V_2\}$, which is not prime. So let us assume that $d \geq 2$. Write $d = d_1 + d_2$ with $d_1, d_2 > 0$, and pick open sets $C_1 \subset \text{Gr}(d_1, A)$ and $C_2 \subset \text{Gr}(d_2, A)$ with the following properties (cf. Lemma 6.11):

1. There are $W_1 \in C_1$ and $W_2 \in C_2$ such that $W_1 + W_2 \subset V_2$;

2. For any $W_1 \in C_1$ and $W_2 \in C_2$ the subspaces $W_1$, $W_2$, and $V_1$ are independent.

Fix $W_1 \in C_1$ and $W_2 \in C_2$ with $W_1 + W_2 \subset V_2$ and pick $a \in V_2$ so that $a \not\in V_1 + W_1$ and $a \not\in V_1 + W_2$. Due to [22, Th. 7.5] the sets $\uparrow C_1$ and $\uparrow C_2$ are open in $\text{Max}^0 A$, and from Lemma 6.17 it follows that

$$\uparrow C_1 \cap \tilde{a} \not\subset U_{V_1,V_2} \quad \text{and} \quad \uparrow C_2 \cap \tilde{a} \not\subset U_{V_1,V_2}. \quad (6.2)$$
Notice also that
\[ (\uparrow C_1 \cap \mathring{a}) \cap (\uparrow C_2 \cap \mathring{a}) = \uparrow (C_1 + C_2) \cap \mathring{a}. \] (6.3)

By independence, for any \( W \in C_1 + C_2 \) we have either \( W \nsubseteq V_2 \) or \( W + V_1 = V_2 \), and thus either \( W \nsubseteq V_2 \) or \( a \in W + V_1 \). Therefore, by Lemma 6.17, we have \( \uparrow (C_1 + C_2) \cap \mathring{a} \subset U_{V_1, V_2} \), and, due to (6.2) and (6.3), we see that \( U_{V_1, V_2} \) is not prime. Finally, if the codimension of \( V_1 \) in \( V_2 \) is infinite then \( U_{V_1, V_2} \) is prime, by Lemma 6.18.

### Universal bundles versus open support topology

Let \( A \) be a topological vector space. The identity \( \text{id} : \text{Sub}^0 A \to \text{Sub}^0 A \) is the kernel map of a quotient vector bundle over \( \text{Sub}^0 A \) that satisfies the open support property. However, as we shall see now, this is not in general a spectral vector bundle because the spectral kernel may fail to be continuous. In addition we show that the open support property does not in general entail having a closed zero section.

We shall denote by \( U^0 A \) the bundle which is classified by the inclusion \( \text{Max}^0 A \to \text{Sub}^0 A \).

**6.20. Theorem.** Let \( A \) be a Hausdorff vector space.

1. If \( \dim A = \infty \) the open support property for \( U^0 A \) holds but its spectral kernel is not continuous.

2. If \( \dim A < \infty \) then \( U^0 A \) is sober (and thus spectral).

**Proof.** Let \( \kappa \) and \( \mathfrak{t} \) be the kernel map and the spectral kernel map of \( U^0 A \) (\( \kappa \) is the identity on \( \text{Max} A \)). Then \( \kappa \) = \( \mathfrak{t} \circ \text{sob} \). Assuming first that \( \dim A = \infty \), from Lemma 6.18 it follows that \( \emptyset = U_{0,A} \) is a prime open set of \( \text{Max}^0 A \). Given any \( V \in \text{Max}^0 A \) we have \( \mathfrak{t}(\text{sob}(V)) = \kappa(V) = V \). If \( \mathfrak{t} \) were continuous then from Theorem 5.13 we would conclude, since \( \emptyset \subset V \) for all \( V \in \text{Max}^0 A \), that \( \mathfrak{t}(\emptyset) = V \) for all \( V \in \text{Max}^0 A \), a contradiction. If \( A \) has finite dimension then it is Euclidean and, by Theorem 6.19, the only prime open sets are of the form \( \text{sob}(V) \) for \( V \in \text{Max}^0 A \). This means that \( \text{Max}^0 A \) is sober, and, by Lemma 5.8, we conclude that \( \mathfrak{t} \) is continuous. Hence, for finite dimensional \( A \) the bundle \( U^0 A \) is sober.

In addition, we mention the following simple consequence of Theorem 6.7:

**6.21. Corollary.** Let \( A \) be a first countable topological vector space such that \( \dim A > 2 \). Then the zero section of \( U^0 A \) is not closed.

**Proof.** By [22, Th. 5.7], the kernel of a quotient vector bundle with closed zero section must be Fell continuous, so the result follows immediately from Theorem 6.7.

THEORY AND APPLICATIONS OF CATEGORIES (ISSN 1201-561X) will disseminate articles that significantly advance the study of categorical algebra or methods, or that make significant new contributions to mathematical science using categorical methods. The scope of the journal includes: all areas of pure category theory, including higher dimensional categories; applications of category theory to algebra, geometry and topology and other areas of mathematics; applications of category theory to computer science, physics and other mathematical sciences; contributions to scientific knowledge that make use of categorical methods.

Articles appearing in the journal have been carefully and critically refereed under the responsibility of members of the Editorial Board. Only papers judged to be both significant and excellent are accepted for publication.

Full text of the journal is freely available from the journal’s server at http://www.tac.mta.ca/tac/. It is archived electronically and in printed paper format.

Subscription information Individual subscribers receive abstracts of articles by e-mail as they are published. To subscribe, send e-mail to tac@mta.ca including a full name and postal address. For institutional subscription, send enquiries to the Managing Editor, Robert Rosebrugh, rrosebrugh@mta.ca.

Information for authors The typesetting language of the journal is T\LaTeX, and \texttt{LaTeX2e} is required. Articles in PDF format may be submitted by e-mail directly to a Transmitting Editor. Please obtain detailed information on submission format and style files at http://www.tac.mta.ca/tac/.
