Abstract. Any real hypersurface of a Kähler manifold carries a natural almost contact metric structure. There are four basic classes of real hypersurfaces of a Kähler manifold with respect to the induced almost contact metric structure. In this paper we study the basic classes of real hypersurfaces of a complex space form in terms of their Riemannian curvatures.

1. Introduction

Let $\overline{M}^{2n+2}(J, G)$ be an almost Hermitian manifold with almost complex structure $J$ and Riemannian metric $G$: $J^2 = -\text{Id}$, $G(JX, JY) = G(X, Y)$, $X, Y \in \mathfrak{X} M^{2n+2}$.

If $M^{2n+1}$ is a hypersurface in $\overline{M}^{2n+2}$ with a unit normal vector field $N$, then there arises naturally an almost contact metric structure $(\varphi, \xi, \eta, g)$ on $M^{2n+1}$ in the following way [3, 10, 12]:

$$
\xi = -JN, \quad g = G|_M, \quad \varphi = J - \eta \otimes N, \\
\eta(X) = g(\xi, X), \quad X \in \mathfrak{X} M^{2n+1}.
$$

Let $\nabla$ and $\nabla'$ be the Levi-Civita connections on $M^{2n+1}$ and $\overline{M}^{2n+2}$, respectively. We denote by $\Phi$ the fundamental 2-form of the structure $(\varphi, \xi, \eta, g)$

$$
\Phi(X, Y) = g(X, \varphi Y), \quad X, Y \in \mathfrak{X} M^{2n+1}
$$

and by $F' = -\nabla' \Phi, F = \nabla \Phi$. If $A$ is the shape operator and $h(X, Y) = g(AX, Y), \quad X, Y \in \mathfrak{X} M^{2n+1}$ is the second fundamental tensor of $M^{2n+1}$,
then the Gauss and Weingarten formulas
\[ \nabla_X^e Y = \nabla_X Y + h(X, Y)N, \quad \nabla_X^e N = -AX, \quad X, Y \in \mathfrak{X}M^{2n+1} \]

imply immediately
\[ (\nabla_X^e \eta)Y = (\nabla_X^e \eta)Y, \]
\[ (\nabla_X J)Y = (\nabla_X \varphi)Y + \{h(X, \varphi Y) + (\nabla_X \eta)Y\}N - \eta(Y)AX + h(X, Y)\xi, \]
\[ F'(X, Y, Z) = F(X, Y, Z) + \eta(Z)h(X, Y) - \eta(Y)h(X, Z). \]

For any point \( p \in M \) we have
\[ T_p \bar{M} = T_p M \oplus N_p, \quad N_p \perp T_p M, \]
\[ T_p M = D_p \oplus \xi_p, \quad \xi_p \perp D_p. \]

\( D = \{D_p, p \in M\} \) is the contact distribution, and \( \{\xi_p; p \in M\} \) is the vertical distribution of \( M \). There exists a second shape operator \( A \), acting in \( M \). The actions of the shape operators \( \bar{A} \) and \( A \) as are follows:
\[ A: \quad T_p \bar{M} \to T_p M \]
\[ X \mapsto AX = -\nabla_X^e N, \quad \bar{A}: \quad T_p M \to D_p \]
\[ X \mapsto \bar{A}X = \nabla_X \xi. \]

If \( \bar{M}^{2n+2}(J, G) \) is Kählerian \((\nabla' J = 0)\), then the following formulas are an immediate consequence from the above formulas [12]:
\[ (\nabla_X \varphi)Y = \eta(Y)AX - h(X, Y)\xi, \]
\[ (\nabla_X \eta)Y = F(X, \varphi Y, \xi) = -h(X, \varphi Y), \]
\[ AX = -\varphi AX + h(X, \xi)\xi, \quad \varphi AX = AX, \]
\[ 2d\eta(X, Y) = h(Y, \varphi X) - h(X, \varphi Y) \]
\[ = 2d\eta(\varphi X, \varphi Y) + \eta(X)h(\varphi Y, \xi) - \eta(Y)h(\varphi X, \xi), \quad (1) \]
\[ (L_\xi g)(X, Y) = -\{h(Y, \varphi X) + h(X, \varphi Y)\} \]
\[ = -(L_\xi g)(\varphi X, \varphi Y) - \eta(X)h(\varphi Y, \xi) - \eta(Y)h(\varphi X, \xi), \quad (2) \]
\[ d\Phi = 0, \]
\[ N(X, Y) = [\varphi, \varphi](X, Y) + 2d\eta(X, Y)\xi \]
\[ = \eta(X)(\varphi AY - A\varphi Y) - \eta(Y)(AAX - A\varphi X), \]
\[ N(X, Y, Z) = -\eta(X)\{h(Y, \varphi Z) + h(Z, \varphi Y)\} \]
\[ + \eta(Y)\{h(X, \varphi Z) + h(Z, \varphi X)\}, \]
\[ F(X, Y, Z) = \eta(Y)h(X, Z) - \eta(Z)h(X, Y), \quad (3) \]
\[ h(X, Y) = -F(X, Y, \xi) = -p(X, Y), \quad (4) \]
\[ h(\xi, Z) = F(\xi, \xi, Z) = \omega(Z) = (L_\xi g)(\varphi Z, \xi) = -2d\eta(\varphi Z, \xi). \]
The function \( \nu = h(\xi, \xi) \) cannot be expressed by \( F \).
If, moreover, \( \bar{M}^{2n+2}(c) \) is a complex space form, i.e. Kähler manifold with constant holomorphic sectional curvature \( c \), then the equations of Gauss and Codazzi are [2]

\[
R(X, Y, Z, U) = \left\{ \begin{array}{l}
\frac{c}{4} [g(Y, *) \wedge g(X, *) + \Phi(Y, *) \wedge \Phi(X, *)] \\
- 2\Phi(X, Y) \cdot \Phi + h(Y, *) \wedge h(X, *) \end{array} \right\}(Z, U),
\]

\[
g((\nabla_X A)Y - (\nabla_Y A)X, Z) = (\nabla_X h)(Y, Z) - (\nabla_Y h)(X, Z)
= \frac{c}{4} [\eta \wedge \Phi(Z, *)](X, Y) + 2\eta(Z)\Phi(X, Y).
\]

Alexiev and Ganchev introduced in [1] twelve basic classes \( W_i \), \( i = 1, \ldots, 12 \), of almost contact metric manifolds with respect to the symmetries of the tensor field \( F \). By using this classification Ganchev and Hristov obtained in [6] the sixteen classes of real hypersurfaces of a Kähler manifold and described them in terms of their second fundamental tensor.

**Theorem 1.1.** ([6]) Let \( \bar{M}^{2n+2}(J, G) \), \( (n \geq 2) \) be a Kähler manifold. Any real hypersurface \( M^{2n+1}(\varphi, \xi, \eta, g) \) of \( \bar{M}^{2n+2} \) is in the class \( W_1 \oplus W_2 \oplus W_4 \oplus W_6 \).

The four basic classes \( W_1, W_2, W_4 \) and \( W_6 \) generate sixteen classes of real hypersurfaces, which are characterized in terms of their second fundamental tensor \( h \) as follows:

i) \( W_0 \) : \( (W_0 \subset W_i, \ i = 1, 2, 4, 6) \quad h \equiv h_0, \)

\( h_0(X, Y) = \nu(\eta \otimes \eta)(X, Y); \)

ii) \( W_1 \) : \( h \equiv h_1 + h_0, \quad h_1(X, Y) = (\eta \otimes \phi + \omega \otimes \eta)(X, Y); \)

iii) \( W_2 \) : \( h \equiv h_2 + h_0, \quad h_2(X, Y) = \frac{f(\xi)}{2n} g(hX, hY), \quad \text{Tr } h \neq 0; \)

iv) \( W_4 \) : \( h \equiv h_4 + h_0, \quad h_4(X, Y) = \frac{f(\xi)}{2n} g(hX, hY) - d\eta(\varphi X, hY), \)

\( \text{Tr } h = 0; \)

v) \( W_6 \) : \( h \equiv h_6 + h_0, \quad h_6(X, Y) = \frac{1}{2} (L_\xi g)(\varphi X, hY); \)

vi) \( W_i \oplus W_j \) : \( h \equiv h_i + h_j + h_0, \quad i, j \in \{1, 2, 4, 6\}, i \neq j; \)

xii) \( W_i \oplus W_j \oplus W_k \) : \( h \equiv h_i + h_j + h_k + h_0, \quad i, j, k \in \{1, 2, 4, 6\}, i \neq j \neq k; \)

xvi) \( W_1 \oplus W_2 \oplus W_4 \oplus W_6 \) : \( h \equiv h_1 + h_2 + h_4 + h_6 + h_0. \)
Remark 1.1. If $n = 1$, then it follows that the class $W_4$ is empty [4]. In this case there arise 8 classes of real hypersurfaces of a 4-dimensional Kähler manifold.

Remark 1.2. With respect to the theory of almost contact metric manifolds, the class:

- $W_0$ is exactly the class of cosymplectic manifolds, characterized by
  \[ F = 0, \quad W_0 \subset W_i, \quad i = 1, 2, \ldots, 12, \]

- $W_2$ is exactly the class of $\alpha$-Sasakian manifolds, characterized by
  \[ N = 0, \quad d\eta = \alpha \Phi, \quad \alpha \neq 0, \]

- $W_2 \oplus W_4$ is exactly the class of quasi-Sasakian manifolds, characterized by
  \[ N = d\Phi = 0, \]

- $W_6 \oplus W_1$ is exactly the class of almost cosymplectic manifolds, characterized by
  \[ d\eta = d\Phi = 0, \]

- $W_2 \oplus W_3 \oplus W_4 \oplus W_5 \oplus W_9 \oplus W_10$ is exactly the class of normal manifolds, characterized by $N = 0$.

Similar questions were considered in [4, 5].

2. Preliminaries

In this section we shall use the notion of a complexification of an almost contact metric vector space and of the tangent bundle of an almost contact metric manifold. We shall consider the complex linear extension of real tensors and their essential components (which may not be zero) with respect to the standard complex coordinates (e.g. [8]).

The following results are the odd-dimensional analogues of the well known decomposition of the curvature tensor in an almost Hermitian manifold [11].

Let $V^{2n+1}(\varphi, \xi, \eta, g)$ be an almost contact metric vector space and $V^c = D^c \oplus \{\xi\} = D^{1,0} \oplus D^{0,1} \oplus \{\xi\}$ be its complexification. $D^{1,0}$ and $D^{0,1}$ are $(+i)$- and $(-i)$-eigenspaces of $\varphi$. $D^{1,0} = \text{span}\{Z_\alpha = e_\alpha - i\varphi e_\alpha\}$, $D^{0,1} = \text{span}\{Z_\bar{\alpha} = e_\alpha + i\varphi e_\alpha\}$, $Z_0 = \xi$, where $\{e_\alpha, \varphi e_\alpha, \xi, \alpha = 1, \ldots n\}$ is an orthonormal basis of $V$. $\mathcal{R}$ denotes the set of all Riemannian-like curvature tensors:

\[
\mathcal{R} = \{ R \in \otimes^4 V^*; \quad R(X, Y, Z, U) = -R(Y, X, Z, U) = -R(X, Y, U, Z), \]

\[
\sigma_{(X,Y,Z)} R(X, Y, Z, U) = 0 \}.
\]
Further $\rho_R, \tilde{\rho}_R, \hat{\rho}_R$ are the Ricci-type contractions associated with $R \in \mathcal{R}$ and $\tau_R, \tilde{\tau}_R, \hat{\tau}_R$ are the corresponding scalar curvatures:

$$
\rho_R(X, Y) = \sum_{i=1}^{2n+1} R(e_i, X, Y, e_i) = g(Q_R(X), Y)
$$

$$
\tau_R = \sum_{i,j=1}^{2n+1} R(e_i, e_j, e_j, e_i)
$$

$$
\rho_R^*(X, Y) = \sum_{i=1}^{2n+1} R(e_i, X, Y, \varphi e_i) = g(\hat{Q}_R(X), Y)
$$

$$
\tau_R^* = \sum_{i,j=1}^{2n+1} R(e_i, e_j, \varphi e_j, \varphi e_i)
$$

$$
\hat{\rho}_R(X, Y) = R(\xi, X, Y, \xi) = g(\tilde{Q}_R(X), Y)
$$

$$
\hat{\tau}_R = \sum_{i=1}^{2n+1} R(\xi, e_i, e_i, \xi)
$$

where $\{e_i, e_{2n+1} = \xi\}$ is an orthonormal basis of $T_p M, p \in M$.

Let $\mathcal{L}$ be the vector space of all $(0, 2)$-tensors over $T_pM$. In [9] it is proved that $\mathcal{L} = \bigoplus_{i=1}^9 \mathcal{L}_i$, where $\mathcal{L}_i$ are mutually orthogonal, $U(n) \times 1$-invariant and irreducible spaces. $\mathcal{L}_i$ are described by the following symmetries for the essential components for $L \in \mathcal{L}$ with complex contraction $\mu = g^{\alpha\beta}L_{\alpha\beta}$:

- $\mathcal{L}_1 : L_{\alpha\beta} = L_{\beta\alpha} = \frac{\mu}{n}g_{\alpha\beta}, \quad \mu = \bar{\mu}$,
- $\mathcal{L}_2 : L_{\alpha\beta} = L_{\beta\alpha}, \quad \mu = \bar{\mu}$,
- $\mathcal{L}_3 : L_{\alpha\beta} = L_{\beta\alpha}$
- $\mathcal{L}_4 : L_{\alpha\beta} = -L_{\beta\alpha} = \mu \frac{n}{\mu} \Phi_{\alpha\beta}, \quad \mu = -\bar{\mu}$,
- $\mathcal{L}_5 : L_{\alpha\beta} = -L_{\beta\alpha}, \quad \mu = -\bar{\mu}$,
- $\mathcal{L}_6 : L_{\alpha\beta} = -L_{\beta\alpha}$
- $\mathcal{L}_7 : L_{0\alpha} = L_{0\alpha}$
- $\mathcal{L}_8 : L_{0\alpha} = -L_{0\alpha}$
- $\mathcal{L}_9 : L_{00}$

By using appropriate involutive isometries, commuting with the Lie group $\mathcal{U}(n) \times 1$, analogously to [11], we obtain the following
Theorem 2.1. (partial decomposition) The space \( \mathcal{R} \) is decomposable into mutually orthogonal and \( \mathcal{U}(n) \times 1 \)-invariant factors as follows

\[
\mathcal{R} = h\mathcal{R}_1 \oplus h\mathcal{R}_{12}^+ \oplus h\mathcal{R}_{13}^+ \oplus h\mathcal{R}_{11}^+ \oplus h\mathcal{R}_{12}^+ \oplus h\mathcal{R}_{13}^+ \oplus h\mathcal{R}_{2}^+. 
\]

The characteristic conditions for the factors in terms of the essential components, are

\[
h\mathcal{R} = h\mathcal{R}_3 \oplus h\mathcal{R}_3^+ = \{ R \in \mathcal{R}; R_{\alpha\beta\gamma\delta}, R_{\alpha\beta\gamma\delta}, R_{\alpha\beta\gamma\delta}, R_{\alpha\beta\gamma\delta} - \text{essential} \},
\]

\[
h\mathcal{R}_3 = \{ R \in h\mathcal{R}; R_{\alpha\beta\gamma\delta} - \text{essential} \},
\]

\[
h\mathcal{R}_3 = h\mathcal{R}_2 \oplus h\mathcal{R}_2^+ = \{ R \in h\mathcal{R}; R_{\alpha\beta\gamma\delta} = 0 \},
\]

\[
h\mathcal{R}_2 = \{ R \in h\mathcal{R}; R_{\alpha\beta\gamma\delta} - \text{essential} \},
\]

\[
h\mathcal{R}_2 = h\mathcal{R}_1 \oplus h\mathcal{R}_1^+ = \{ R \in h\mathcal{R}; R_{\alpha\beta\gamma\delta} = 0 \},
\]

\[
h\mathcal{R}_1 = \{ R \in h\mathcal{R}; R_{\alpha\beta\gamma\delta} = 2R_{\alpha\gamma\beta\delta} - R_{\alpha\delta\gamma\beta} \}.
\]

\[
v\mathcal{R} = v\mathcal{R}_2 \oplus v\mathcal{R}_2^+ = \{ R \in \mathcal{R}; R_{0\alpha\beta\gamma}, R_{0\alpha\beta\gamma}, R_{0\alpha\beta\gamma} - \text{essential} \},
\]

\[
v\mathcal{R}_2 = \{ R \in v\mathcal{R}; R_{0\alpha\beta\gamma} - \text{essential} \},
\]

\[
v\mathcal{R}_2 = v\mathcal{R}_1 \oplus v\mathcal{R}_1^+ = \{ R \in v\mathcal{R}; R_{0\alpha\beta\gamma} = 0 \},
\]

\[
v\mathcal{R}_1 = \{ R \in v\mathcal{R}_2; R_{0\alpha\beta\gamma} = 2R_{0\gamma\beta\alpha} - R_{0\alpha\beta\gamma} \}.
\]

\[
v\mathcal{R}_1 = \{ R \in v\mathcal{R}_2; R_{0\alpha\beta\gamma} = 0 \} \iff R_{0\alpha\beta\gamma} = R_{0\beta\alpha\gamma} \}.
\]

\[
w\mathcal{R} = w\mathcal{R}_1 \oplus w\mathcal{R}_1^+ = \{ R \in \mathcal{R}; R_{0\alpha\beta\gamma}, R_{0\alpha\beta\gamma} - \text{essential} \},
\]

\[
w\mathcal{R}_1 = \{ R \in w\mathcal{R}; R_{0\alpha\beta\gamma} = 0, R_{0\alpha\beta\gamma} - \text{essential} \},
\]

\[
w\mathcal{R}_1 = \{ R \in w\mathcal{R}; R_{0\alpha\beta\gamma} = 0, R_{0\alpha\beta\gamma} - \text{essential} \}.
\]

By using the self-conjugate projections \( p_i, q_i, r_i, i = 1, 2, s, t, u \), commuting with \( \mathcal{U}(n) \times 1 \), we describe their kernels and images, and following the scheme in [7, 11] we get

Theorem 2.2. (complete decomposition) The space \( \mathcal{R} \) is decomposable into 18 mutually orthogonal, \( \mathcal{U}(n) \times 1 \)-invariant and irreducible factors:

\[
\mathcal{R} = h\mathcal{R}_{11} \oplus h\mathcal{R}_{12} \oplus h\mathcal{R}_{13} \oplus h\mathcal{R}_{11}^+ \oplus h\mathcal{R}_{12}^+ \oplus h\mathcal{R}_{13}^+ \oplus h\mathcal{R}_{2}^+ 
\]

\[
\oplus h\mathcal{R}_{31}^+ \oplus h\mathcal{R}_{32} \oplus h\mathcal{R}_{33}^+ 
\]

\[
\oplus v\mathcal{R}_{11} \oplus v\mathcal{R}_{12} \oplus v\mathcal{R}_{11}^+ \oplus v\mathcal{R}_{12}^+ \oplus v\mathcal{R}_{2}^+ 
\]

\[
\oplus w\mathcal{R}_{11} \oplus w\mathcal{R}_{12} \oplus w\mathcal{R}_{11}^+ \; ;
\]

3. Riemannian Curvature Identities in the Basic Classes of Real Hypersurfaces of a Complex Space Form

In the sense of [8], we give the following

**Lemma 3.1.** The characterization conditions for the basic classes of real hypersurfaces \(M^{2n+1}(\varphi, \xi, \eta, g)\) of a Kähler manifold in terms of the essential components and essential complex equalities for the fundamental tensors, are as follows:

- \(W_1: \ h_{a0} = L_{a0} = F_{00a} = \omega_{a} = -2i\eta_{a0} = i(\mathcal{L}_\xi g)_{a0} = -iN_{a00}\)
- \(W_2: \ h_{a\beta} = \frac{i}{2}L_{a\beta} = -i\eta_{a\beta} = -F_{a\beta0} = -F_{\beta a0} = -\frac{f(\xi)}{2n}g_{a\beta}\)
- \(W_4: \ h_{a\beta} = \frac{i}{2}L_{a\beta} = -i\eta_{a\beta} = -F_{a\beta0} = -F_{\beta a0}, \ f(\xi) = \text{Tr} \ h = 0\)
- \(W_6: \ h_{a\beta} = \frac{i}{2}(\mathcal{L}_\xi g)_{a\beta} = -F_{a\beta0} = -F_{\beta a0} = \frac{i}{2}N_{0a\beta}, \ L \equiv 0\)

where \(L\) is the Levi form.

Using the relations between the shape operators, we get

**Lemma 3.2.** The characterization conditions for the basic classes \(W_i, \ i = 1, 2, 4, 6\) with respect to the shape operators \(\mathcal{A}\) and \(A\) are as follows:

- \(W_1: \ \mathcal{A} = \varphi A, \ g(AX, Y) = -(\eta \otimes \omega \circ \varphi)(X, Y), \ \mathcal{A}^* = -(\omega \circ \varphi) \otimes \xi, \ \text{Tr} \ A = 0, \ \text{Tr} (A \circ \varphi) = 0\)
- \(W_2: \ A = \mathcal{A}^* = \varphi \circ A \circ \varphi^{-1} = -\frac{\delta \Phi(\xi)}{2n} \varphi, \ \text{Tr} \ A = 0, \ \text{Tr} (A \circ \varphi) \neq 0\)
  \(\text{or equivalently:} \ \varphi \circ A = A \circ \varphi = -\frac{\delta \Phi(\xi)}{2n} \varphi, \ \text{Tr} \ A = \text{Tr} \ h = -\text{Tr} \ A + \nu\)
- \(W_4: \ \mathcal{A} = \mathcal{A}^* = \varphi \circ A \circ \varphi^{-1}, \ \text{Tr} \ A = 0, \ \text{Tr} (A \circ \varphi) = 0\)
  \(\text{or equivalently:} \ \varphi \circ A = A \circ \varphi \ \text{Tr} \ A = \text{Tr} \ h = \nu\)
- \(W_6: \ A = \mathcal{A}^* = -\varphi \circ A \circ \varphi^{-1}, \ \text{Tr} \ A = 0, \ \text{Tr} (A \circ \varphi) = 0\)
  \(\text{or equivalently:} \ \varphi \circ A = -A \circ \varphi \ \text{Tr} \ A = \text{Tr} \ h = \nu\)

Here \(\mathcal{A}^*\) is the operator, \(g\)-conjugate to \(A\) and \(\delta \Phi\) is the codifferential of \(\Phi\).

The equation of Codazzi implies:

**Lemma 3.3.** The essential components of the covariant derivatives of the shape operator \(A\) and of the second fundamental tensor \(h\) of a real hypersurface of a complex space form \(M^{2n+2}(c)\) satisfy the following equalities:
i) \((\nabla_{\alpha} A)_{\beta} - (\nabla_{\beta} A)_{\alpha} = 0 \iff (\nabla_{\alpha} h)_{\beta C} - (\nabla_{\beta} h)_{\alpha C} = 0, C \in \{\gamma, \tilde{\gamma}, 0\};\)

ii) \((\nabla_{\alpha} A)_{\beta} - (\nabla_{\beta} A)_{\alpha} = \frac{c}{2} \Phi_{\alpha\beta} \xi \iff (\nabla_{\alpha} h)_{\beta 0} - (\nabla_{\beta} h)_{\alpha 0} = \frac{c}{2} \Phi_{\alpha\beta} = -\frac{c}{2} i g_{\alpha\beta};\)

iii) \((\nabla_{\alpha} A)_{0} - (\nabla_{0} A)_{\alpha} = -\frac{c}{4} \varphi Z_{\alpha} = -i \frac{c}{4} Z_{\alpha} \iff (\nabla_{\alpha} h)_{0\beta} - (\nabla_{0} h)_{\alpha\beta} = \frac{c}{2} \Phi_{\alpha\beta} = -\frac{c}{2} i g_{\alpha\beta}.

The Gauss equation and Lemma 3.1 imply

**Lemma 3.4.** Let \(M^{2n+1}(\varphi, \xi, \eta, g)\) be real hypersurface of a complex space form \(M^{2n+2}(c)\). Then the Riemannian curvature tensor \(R\) satisfies in terms of the essential components the following identities:

1. \(R_{\alpha\beta\gamma\delta} = \frac{c}{2} (g_{\alpha\beta} g_{\gamma\delta} + g_{\beta\gamma} g_{\alpha\delta} + h_{\beta\gamma} h_{\alpha\delta} - h_{\alpha\gamma} h_{\beta\delta}) = \frac{c}{2} (\pi_{1} + \pi_{2})_{\alpha\beta\gamma\delta} + h_{\beta\gamma} h_{\alpha\delta} - h_{\alpha\gamma} h_{\beta\delta}\)

2. \(R_{\alpha\beta\gamma\delta} = h_{\beta\gamma} h_{\alpha\delta} - h_{\alpha\gamma} h_{\beta\delta}\)

3. \(R_{\alpha\beta\gamma\delta} = h_{\beta\gamma} h_{\alpha\delta} h_{\alpha\gamma} h_{\beta\delta}\)

4. \(R_{\alpha\beta\gamma\delta} = h_{\beta\gamma} h_{\alpha\delta} - h_{\alpha\gamma} h_{\beta\delta}\)

5. \(R_{\alpha\beta\gamma\delta} = h_{\alpha\beta} h_{0\gamma} - h_{\alpha\gamma} h_{0\beta}\)

6. \(R_{\alpha\beta\gamma\delta} = h_{\alpha\beta} h_{0\gamma} - h_{\alpha\gamma} h_{0\beta}\)

7. \(R_{\alpha\beta\gamma\delta} = h_{\alpha\beta} h_{0\gamma} - h_{\alpha\gamma} h_{0\beta}\)

8. \(R_{\alpha\beta\gamma\delta} = \frac{c}{4} g_{\alpha\beta} + \nu h_{\alpha\beta} - h_{\alpha\beta} h_{0\beta}\)

9. \(R_{\alpha\beta\gamma\delta} = \nu h_{\alpha\beta} - h_{\alpha\beta} h_{0\beta}\).

Using Lemma 3.1, Lemma 3.4 and Theorems 2.1 and 2.2, we express the essential components and the decomposition of the Riemannian curvature tensor \(R\):

**Theorem 3.1.** Let \(M^{2n+1}(\varphi, \xi, \eta, g)\) be in one of the basic classes \(W_{1}, W_{2}, W_{3}, W_{4}, W_{5}\) of real hypersurfaces of a complex space form \(M^{2n+2}(c)\). Then the Riemannian curvature tensor \(R\) satisfies the following identities:

- **\(W_{1}:\)**

  \(R_{\alpha\beta\gamma\delta} = \frac{c}{2} (\pi_{1} + \pi_{2})_{\alpha\beta\gamma\delta},\)

  \(R_{\alpha\beta\gamma\delta} = \frac{c}{4} g_{\alpha\beta} - \omega_{\alpha} \omega_{\beta},\)

  \(R_{\alpha\beta\gamma\delta} = -\omega_{\alpha} \omega_{\beta}\)
and $M \in hR_{11}(\tau = c \frac{n(n+1)}{16}) \oplus wR$;

- $W_2$:
  \[ R_{\alpha \beta \gamma \delta} = \frac{c}{2} (\pi_1 + \pi_2)_{\alpha \beta \gamma \delta} + \frac{f^2(\xi)}{4n^2} g_{\gamma \beta} g_{\alpha \delta}, \]
  \[ R_{\alpha \beta \gamma \delta} = \frac{f^2(\xi)}{4n^2} \begin{vmatrix} g_{\beta \gamma} & g_{\alpha \gamma} \\ g_{\beta \delta} & g_{\alpha \delta} \end{vmatrix}, \]
  \[ R_{0\alpha \beta 0} = \left( \frac{c}{4} - \nu \frac{f(\xi)}{2n} \right) g_{\alpha \beta}, \]

and $M \in hR_2 \oplus wR_{11}(\tilde{\tau} = \frac{cn}{8} - \nu \frac{f(\xi)}{4})$;

- $W_4$:
  \[ R_{\alpha \beta \gamma \delta} = 2(\pi_1 + \pi_2)_{\alpha \beta \gamma \delta} - \eta_{\gamma \delta} \eta_{\alpha \beta}, \]
  \[ R_{\alpha \beta \gamma \delta} = \begin{vmatrix} \eta_{\alpha \gamma} & \eta_{\beta \gamma} \\ \eta_{\alpha \delta} & \eta_{\beta \delta} \end{vmatrix}, \]
  \[ R_{0\alpha \beta 0} = \frac{c}{4} g_{\alpha \beta} + i\nu \eta_{\alpha \beta} \]

and $M \in hR_2 \oplus wR_1$;

- $W_6$:
  \[ R_{\alpha \beta \gamma \delta} = \frac{c}{2} (\pi_1 + \pi_2)_{\alpha \beta \gamma \delta} - \frac{1}{4} (L_{\xi g})_{\alpha \gamma} (L_{\xi g})_{\beta \delta}, \]
  \[ R_{\alpha \beta \gamma \delta} = -\frac{1}{4} \begin{vmatrix} (L_{\xi g})_{\beta \gamma} & (L_{\xi g})_{\alpha \gamma} \\ (L_{\xi g})_{\beta \delta} & (L_{\xi g})_{\alpha \delta} \end{vmatrix}, \]
  \[ R_{0\alpha \beta 0} = \frac{c}{4} g_{\alpha \beta}, \]
  \[ R_{0\alpha \beta 0} = \frac{i}{2} \nu (L_{\xi g})_{\alpha \beta} \]

and $M \in hR_1 \oplus hR_{1/2} \oplus wR_{11}(\tilde{\tau} = \frac{cn}{8}) \oplus wR_{1/2}$.
