UNIFORM ATTRACTORS IN SUP-NORM FOR SEMI LINEAR PARABOLIC PROBLEM AND APPLICATION TO THE ROBUST STABILITY THEORY

Oleksiy Kapustyan, Olena Kapustian, Oleksandr Stanzytskyi, and Ihor Korol

Abstract. In this paper we establish the existence of the uniform attractor for a semi linear parabolic problem with bounded non autonomous disturbances in the phase space of continuous functions. We applied obtained results to prove the asymptotic gain property with respect to the global attractor of the undisturbed system.

1. Introduction

Stability property of stationary points plays an important role in robust control theory. The notion of input-to-state stability, firstly appeared in [23] now is widely used to nonlinear systems of different nature [24]. Other approaches in the control theory for nonlinear systems can be found in [2]–[11]. In recent years there have appeared many papers devoted to adaptation of input-to-state stability theory to infinite dimensional case [7]–[13]. One of the central object in the qualitative theory of dissipative infinite-dimensional systems is a global attractor [19], [22]. Stability properties of global attractors, including impulsive perturbations, can be found in [1]–[5], [9]. Recently in [6], [21] there have been obtained results about input-to-state stability and asymptotic gain properties with respect to global attractors of semi linear heat and wave equations in $L^2$ space. This results requires that the corresponding non autonomous problem generated semi process family with uniform attractor [3] which tends to the global attractor of undisturbed system. In the present paper we apply this scheme to the case of the phase space $C_0$ of continuous functions supplied with sup-norm. Similar results for other type of perturbations were studied in [25], [26]. The work consists of two parts. In the first part we set the problem, provide necessary definitions and auxiliary results,
and prove that under suitable assumptions mild solutions of the perturbed system
generate a semi process family on $\mathbb{C}_0$ which has a uniform attractor. In the second
part we use this result to establish the asymptotic gain properties with respect to
the global attractor of the unperturbed system.

2. Setting of the problem and uniform attractors

We consider the following problem

\begin{equation}
\begin{cases}
\frac{\partial u}{\partial t} = Au + f(u) + h(t, x), & (t, x) \in (0, \infty) \times \Omega, \\
u|_{\partial \Omega} = 0, \\
u(0, x) = u_0(x),
\end{cases}
\end{equation}

where $u(t, x)$ is an unknown function, $\Omega \subset \mathbb{R}^N$ is a bounded domain with sufficiently
smooth boundary,

\[ Au = \sum_{i,j=1}^{N} \frac{\partial}{\partial x_j} \left( a_{ij}(x) \frac{\partial u}{\partial x_i} \right) + \sum_{i=1}^{n} b_i(x) \frac{\partial u}{\partial x_i} + c(x)u. \]

Assume that

\[ (2.2) \quad -A \text{ is a strongly elliptic self adjoint operator with bounded sufficiently smooth coefficients,} \]

\[ f: \mathbb{R} \to \mathbb{R} \text{ is locally Lipschitz, } f(0) = 0 \text{ and} \]

\[ (2.3) \quad \exists C > 0 \text{ such that } \forall |s| \geq C \quad s \cdot f(s) \leq 0. \]

Assume that $h \in L^\infty(0, +\infty; X)$, where

\[ X = C_0(\Omega) = \{v \in C(\overline{\Omega}) | v = 0 \text{ on } \partial \Omega\} \]
supplied with the sup-norm $\|v\|_X = \sup_{x \in \Omega} |v(x)|$. In the future we will use the spaces

\[ H^1 = W^{1,2}(\Omega), \quad H^1_0 = \{v \in H^1, v|_{\partial \Omega} = 0\}, \quad H^2 = W^{2,2}(\Omega), \quad L^2 = L^2(\Omega). \]

We will study qualitative behaviour of mild solutions of (2.1) in the phase space $X$.

**Definition 2.1.** The function $u \in C([0, T]; X)$ is a mild solution of (2.1) with initial data $u_0 \in X$ if for all $t \in [0, T]$ we have

\begin{equation}
\begin{aligned}
u(t) &= T(t)u_0 + \int_0^t T(t-s)F(u(s))ds + \int_0^t T(t-s)h(s)ds, \\
\end{aligned}
\end{equation}

where $F: X \to X, F(u)(x) = f(u(x)), T(t)$ is a $C_0$ semigroup of bounded operators, generated by $A$ in $X$.

We prove that for all initial condition $u_0 \in X$ there exists a unique global mild solution of (2.1) with $u(0) = u_0$, which will be denoted by $u(t) = S_h(t, 0, u_0)$.

Taking the set $\Sigma(h)$ of all time shifts of $h$ we show that the semiprocess family $\{S_\sigma\}_{\sigma \in \Sigma(h)}$ (see definition below) has uniform attractor $\Theta_{\Sigma(h)}$ in the phase space
X and, moreover, for the global attractor $\Theta$ of the unperturbed system ($h \equiv 0$) we have:

$$\text{dist}_X(\Theta_{\Sigma(h)}, \Theta) \to 0 \text{ as } h \to 0,$$

where

$$\text{dist}_X(A, B) = \sup_{a \in A} \inf_{b \in B} \|a - b\|_X.$$

Limit equality (2.5) allow us to get the following result concerning robust stability: there exists a continuous strictly increasing function $\gamma$, vanishing at the origin, such that

$$\forall u_0 \in X \quad \lim_{t \to \infty} \|S_h(t, 0, u_0)\|_\Theta \leq \gamma(\|h\|_\infty),$$

where

$$\|u\|_\Theta := \inf_{\xi \in \Theta} \|\xi - u\|_X, \quad \|h\|_\infty = \sup_{t \geq 0} \|h(t)\|_X.$$

To prove (2.5), (2.6) we need some auxiliary results. First let us assume that $h \in L^2_{loc}(0, +\infty; X)$. Then, using Lipschitz continuity of $f$, we can use the classical result [17] (see Th. 1.4, Ch. 6) and claim that for every $u_0 \in X$ there exists $T = T(u_0, h) > 0$ such that there exists a unique mild solution of (2.1), $u \in \mathbb{C}([0, T]; X)$ with $u(0) = u_0$. Moreover, condition (2.3) allow us to use well-known comparison principle [12] and deduce the following estimate holds

$$\|u(t)\|_X \leq M e^{-\lambda t}\|u_0\|_X + \frac{MC_1}{\lambda} + \int_0^t M e^{-\lambda(t-s)}\|h(s)\|_X\ ds,$$

where constant $C_1 > 0$ depends on $f$ and positive constants $M, \lambda$ are taken from the inequality

$$\|T(t)\| \leq M e^{-\lambda t} \quad \forall t \geq 0.$$

This estimate shows that every mild solution is global, i.e., defined on $[0, +\infty)$.

In the sequel we will use the following facts. It is known that $A$ is the infinitesimal generator of an analytic semigroup (still denoted by $T(t)$) in $L^p(\Omega)$, $p \geq 2$ [17]. Both in $L^p(\Omega)$, $p \geq 2$ and in $X$, we have the following estimates [3, 10]: there exist $c > 0$, $\alpha \in (0, 1)$, $\delta \in (\frac{1}{2}, 1)$ such that

$$\forall u_0 \in L^2(\Omega) \quad \|T(t)u_0\|_{H^2} \leq \frac{c}{t} \|u_0\|_{L^2},$$

$$\|3pt\| \forall u_0 \in X \quad \|T(t)u_0\|_{C^{1+\alpha}} \leq \frac{c}{t^\delta} \|u_0\|_X.$$
We consider mild solution of (2.11), i.e. \( u \in C([0, T]; L^2(\Omega)) \),

\[
(2.12) \quad u(t) = T(t)u_0 + \int_0^t T(t-s)g(s) \, ds.
\]

It is known [17] that mild solution of (2.11) is a weak solution of (2.11), i.e. \( u \in L^2(0, T; H_0^1) \) such that \( \forall v \in H_0^1, \forall \eta \in C_0^\infty(0, T) \)

\[
\int_0^T (u(t), v) \eta \, ds + \int_0^T (A^{1/2}u(t), A^{1/2}v) \eta \, ds = \int_0^T (g(t), v) \eta \, ds,
\]

where \((\cdot, \cdot)\) is a scalar product in \( L^2 \), \( \|u\| = \sqrt{(u, u)} \). Moreover, every weak solution \( u \) of (2.11) is a mild continuous of (2.11) in \([0, T]\). Additionally, if \( u_0 \in H_0^1 \) then \( u \in C([0, T]; H_0^1) \cap L^2(0, T; H^2) \), \( u_\tau \in L^2(0, T; L^2) \). All this facts help us to prove the global existence result.

Now we are in position to construct the semi processes family, generated by the equation (2.1).

Let \( h \in L^\infty(0, +\infty; X) \) and let \( \Sigma(h) \subset L^2_{loc}(0, +\infty; X) \), \( (\Sigma(0) = \{0\}) \) be an arbitrary shift invariant (i.e. \( \forall d \in \Sigma(h), \forall s \geq 0 d(s+\cdot) \in \Sigma(h) \)) topological space generated by \( h \).

Let us consider the problem (2.1) where \( h \) is replaced by \( d \in \Sigma(h) \)

\[
\begin{cases}
\frac{\partial u}{\partial t} = Au + f(u) + d(t, x), & (t, x) \in (0, \infty) \times \Omega \\
u|_{\partial \Omega} = 0, \\
u(0, x) = u_0(x),
\end{cases}
\]  

(2.14)

From the previous arguments we deduce that every solution of (2.14) is global. We denote by

\( S_d(t, \tau, u_\tau) \)

the solution of (2.14) at the moment \( t \geq \tau \) with initial data \( (\tau, u_\tau) \in [0, \infty) \times X \). Then the family \( \{S_d(t, \tau, u_\tau)\}_{d \in \Sigma(h)} \) generates a semiprocess family [19], i.e. \( \forall t \geq \tau \geq 0 \ \forall u_\tau \in X \ \forall d \in \Sigma(h) \)

\[
S_d(\tau, \tau, u_\tau) = u_\tau, \\
S_d(t, s, S_d(s, \tau, u_\tau)) = S_d(t, \tau, u_\tau) \ \forall t \geq s \geq \tau, \\
S_d(t + p, \tau + p, u_\tau) = S_d(t, \tau, u_\tau) \ \forall p \geq 0.
\]

Every semiprocess family satisfies the cocycle property

\[
S_d(t + p, 0, u) = S_d(t, 0, S_d(p, 0, u)).
\]

In particular, for \( d \equiv 0 \)

\[
S_0(t + p, 0, u) = S_0(t, 0, S_0(p, 0, u)),
\]

i.e. \( S_0 \) is a semigroup.

It is known [8] that under conditions (2.2), (2.3) the semigroup \( S_0 \) processes a global attractor \( \Theta \subset X \), that is
1) $\Theta$ is a compact set;
2) $\Theta = S_0(t, 0, \Theta) \quad \forall t \geq 0$;
3) for every bounded set $B \subset X$
   \[
   \sup_{u \in B} \operatorname{dist}_X(S_0(t, 0, u), \Theta) \to 0 \quad \text{as} \quad t \to \infty.
   \]

In the sequel we denote for $\Sigma = \Sigma(h)$,
\[
S_\Sigma(t, \tau, B) = \bigcup_{d \in \Sigma} \bigcup_{u \in B} S_d(t, \tau, u).
\]

**Definition 2.2.** A compact set $\Theta \subset X$ is called a uniform attractor of the semiprocess family $\{S_d\}_{d \in \Sigma}$ if for every bounded set $B \subset X$ we have
\[
\text{(2.15)} \quad \operatorname{dist}_X(S_\Sigma(t, 0, B), \Theta) \to 0 \quad \text{as} \quad t \to \infty,
\]
and $\Theta$ is the minimum among all closed sets satisfying (2.15).

The following well known result provides conditions for existence of uniform attractor.

**Lemma 2.3** ([3]). Let $\{S_d\}_{d \in \Sigma}$ be a semiprocess family with a first countable space $\Sigma$, and
1) there exists a bounded set $B_0 \subset X$ such that for every bounded set $B \subset X$
   \[
   \exists T = T(B) \quad \forall t \geq T \quad S_\Sigma(t, 0, B) \subset B_0;
   \]
2) $\forall d_n \in \Sigma \forall t_n \to \infty \forall$ bounded $\{u_n\} \subset X$ the sequence $\{S_{d_n}(t_n, 0, u_n)\}$ is precompact in $X$.

Then $\{S_d\}_{d \in \Sigma}$ has a uniform attractor $\Theta$.
If, additionally, for all $t \geq 0$ the map
\[
\text{(2.16)} \quad X \times \Sigma \ni (u, d) \to S_d(t, 0, u) \subset X
\]
is continuous, then $\Theta$ is negatively invariant, i.e.
\[
\text{(2.17)} \quad \forall t \geq 0 \quad \Theta \subset S_\Sigma(t, 0, \Theta).
\]

**Remark 2.4.** From (2.17) we get inclusion: $\Theta \subset B_0$.

Assume that
\[
\text{(2.18)} \quad h(t, x) = \sum_{j=1}^K h_j(t) \phi_j(x),
\]
where $K \geq 1$, $h_j \in L^\infty(0, +\infty)$, $\phi_j \in X$.

Let us put
\[
W := \text{cl}_{L^2_{loc}(0, +\infty)}^K \{(h_1(\cdot + s), \ldots, h_K(\cdot + s)) \mid s \geq 0\},
\]
\[
\text{(2.19)} \quad \Sigma = \Sigma(h) = \left\{ \sum_{j=1}^K d_j(t) \phi_j(x) \mid \{d_1, \ldots, d_K\} \in W \right\}.
\]
It is known [22] that the set
\[ W_g := \text{cl} L^2_{loc}(0, +\infty) \{ g(\cdot + s) \mid s \geq 0 \} \]
is compact in \( L^2_{loc}(0, +\infty) \) if and only if \( \| g \|_+ := \sup_{t \geq 0} \int_0^{t+1} \| g(s) \|_{X}^2 ds < \infty \). Moreover, such a set is shift-invariant, and \( \forall \xi \in W_g \)
\[ \| \xi \|_+ \leq \| g \|_+. \]
Therefore, the set \( \Sigma \) defined by (2.19) is shift-invariant, and
\[ \forall d \in \Sigma(h) \quad \| d \|_+ \leq \| h \|_{\infty}. \]

**Theorem 2.5.** Assume that conditions (2.2), (2.3), (2.18) take place. Then the semiprocess family \( \{ S_d \}_{d \in \Sigma} \) generated by mild solutions of the problem (2.1), has a uniform attractor \( A_\Sigma \), which satisfies (2.17).

**Proof.** For every \( d \) with \( \| d \|_+ < \infty \) inequality (2.7) implies
\[ \| u(t) \|_X \leq Me^{-\lambda t} \| u_0 \|_X + \frac{MC_1}{\lambda} + \| d \|_+^\frac{1}{2} (1 - e^{-\lambda})^{-\frac{1}{2}}. \]
So, from (2.20) for every \( d \in \Sigma(h) \) we get that for all bounded \( B \subset X \) \( \exists T = T(B) \) \( \forall t \geq T \)
\[ S_\Sigma(t, 0, B) \subset B_0 = \{ u \in X \mid \| u \|_X \leq 1 + C \}, \]
for some positive constant \( C \), which does not depend on \( B \). Therefore, assumption 1) from Lemma 2.3 takes place. Moreover, for every bounded \( B \subset X \) and every \( u(\cdot) \) with \( u(0) = u_0 \) there exists \( K = K(B) \) such that for all \( d \in \Sigma \) and all \( u_0 \in B, t \geq 0 \)
\[ \| f(u(t)) \|_\infty \leq K. \]
Then due to (2.10) for \( t > 0 \) and \( \delta \in \left( \frac{1}{2}, 1 \right) \)
\[ \| u(t) \|_{C^{1+\alpha}} \leq \frac{C}{\delta^\alpha} \| u_0 \|_X + \int_0^t \frac{C}{s^\alpha} K ds + \int_0^t \frac{C}{s^\alpha} \| h \|_{\infty} ds \leq r(t). \]
Due to compact embedding \( C^{1+\alpha} \subset X \) and inclusions: for \( \{ d_n \} \subset \Sigma, \ t_n \to \infty, \)
\[ \| u_0^n \|_X \leq r \]
\[ \xi_n = S_{d_n}(t_n, 0, u_0^n) = S_{d_n}(t_n, t_n - 1, S_{d_n}(t_n - 1, 0, u_0^n)) = \]
\[ = S_{d_n}(\cdot + t_n - 1)(1, 0, S_{d_n}(t_n - 1, 0, u_0^n)) \subset S_\Sigma(1, 0, B_0) \]
for sufficiently large \( n \geq 1 \), where \( B_0 \) is taken from (2.21). So, we conclude that \( \{ \xi_n \} \) is precompact in \( X \), and, therefore, semiprocess family \( \{ S_d \}_{d \in \Sigma} \) possesses a uniform attractor \( \Theta_\Sigma \).

Let us prove (2.17). For this aim we prove the following result.
Lemma 2.6. Assume that for \( d^n = (d_{1n}, \ldots, d_{kn}) \), \( d = (d_1, \ldots, d_k) \)

\[
d^n \to d \quad \text{in} \quad \left( L^2_{\text{loc}}(0, +\infty) \right)^K, \quad u_{0n} \to u_0 \quad \text{in} \quad X.
\]

Then for all \( t \in [0, T] \) we have

\[
u_n(t) = S_{d_n}(t, 0, u_0) \to u(t) = S_d(t, 0, u_0) \quad \text{in} \quad X.
\]

\textbf{Proof.} Due to (2.21) both \( \{u_n\} \) and \( \{f(u_n)\} \) are bounded in \( C([0, T]; X) \). Let us consider \( u_n \) as a weak solution of (2.11) with right side

\[
g_n(t) = f(u_n) + \sum_{j=1}^{K} d_{jn}(t) \varphi_j.
\]

Then \( \{g_n\} \) is bounded in \( L^2(0, T; X) \), \( \{u_n\} \) is bounded in \( L^2(0, T; H^1_0) \), \( \{u_{nt}\} \) is bounded in \( L^2(0, T; H^{-1}) \). So, due to Aubin-Lions Lemma there exists a function \( u \in C([0, T]; L^2) \) such that up to subsequence:

\[
u_n \to u \quad \text{weakly in} \quad L^2(0, T; H^{-1}),
\]

\[
u_n \to u \quad \text{in} \quad L^2(0, T; L^2) \quad \text{and almost everywhere (a.e.) in} \quad (0, T) \times \Omega,
\]

\[
\forall t \in [0, T] \quad u_n(t) \to u(t) \quad \text{weakly in} \quad L^2.
\]

Then \( f(u_n(t, x)) \to f(u(t, x)) \) a.e. and, therefore,

\[
g_n \to g = f(u) + \sum_{j=1}^{K} d_j(t) \varphi \quad \text{weakly in} \quad L^2(0, T; L^2).
\]

So, \( u \) is a weak solution of (2.11) with the right hand side \( g \). Thus, due to the previous arguments we have that \( u \) is a mild solution of (2.11) in \( L^2 \) and, therefore, a mild solution of (2.1) in \( L^2 \). Then \( u \) is a mild solution of (2.1) in \( X \). Indeed, due to the (2.22) and (2.25) \( \forall t \in [0, T] \quad u_n(t) \to u(t) \quad \text{in} \quad X \). Then for all \( t \in [0, T] \)

\[
u(t, \cdot) \in X \Rightarrow f(u(t, \cdot)) \in X \Rightarrow g \in L^2(0, T; X) \Rightarrow u(t) \in S_d(t, 0, u_0).
\]

Lemma is proved.

Property (2.24) implies (2.16), and, therefore, (2.17). Theorem is proved. □

3. Application to the robust stability theory

In this section we want to obtain asymptotic gain property (2.6).

\textbf{Theorem 3.1.} Under conditions (2.2), (2.3), (2.18) problem (2.1) for \( \|h\|_{\infty} \leq R_0 \) possesses asymptotic gain property w.r.t. global attractor \( \Theta \) of the undisturbed \( (h \equiv 0) \) system.

\textbf{Proof.} Let us assume that we have the limit property

\[
dist(\Theta_{\Sigma(h)}, \Theta) \to 0 \quad \text{as} \quad \|h\|_{\infty} \to 0.
\]
Let us prove that \((3.1)\) implies \((2.6)\). Indeed, according to construction \(\Sigma(0) = \{0\}\), and \(h \in \Sigma(h)\). So, for \(u_0 \in X\), \(z \in \Theta_{\Sigma(h)}\), \(t > 0\), \(u(t) = S_h(t, 0, u_0)\) we have: for \(\theta \in \Theta:\)

\[
\|u(t) - \theta\|_X \leq \|u(t) - z\|_X + \|z - \theta\|_X \\
\inf_{\theta \in \Theta} \|u(t) - \theta\|_X \leq \|u(t) - z\|_X + \inf_{\theta \in \Theta} \|z - \theta\|_X \\
\inf_{\theta \in \Theta} \|u(t) - \theta\|_X \leq \inf_{z \in \Theta_{\Sigma(h)}} \|u(t) - z\|_X + \sup_{z \in \Theta_{\Sigma(h)}} \inf_{\theta \in \Theta} \|z - \theta\|_X \\
\|

\|u(t)\|_\Theta \leq \text{dist}_X(u(t), \Theta_{\Sigma(h)}) + \text{dist}_X(\Theta_{\Sigma(h)}, \Theta) \\
\|S_h(t, 0, u_0)\|_\Theta \leq \text{dist}_X(S_{\Sigma(h)}(t, 0, u_0), \Theta_{\Sigma(h)}) + \text{dist}_X(\Theta_{\Sigma(h)}, \Theta).
\]

The first summand in the right part of this inequality tends to zero for every \(h\). Let us put

\[
\gamma(s) := \sup_{\|h\|_\infty \leq s} \text{dist}_X(A_{\Sigma(h)}, A) + s.
\]

Due to \((3.1)\) \(\gamma \in K\) and \(\text{dist}_X(\Theta_{\Sigma(h)}, \Theta) \leq \gamma(\|h\|_\infty)\), so we have the required result. Let us prove \((3.1)\). Assume that \((3.1)\) does not take place. It means that there exists \(h_n \to 0\) in \(L^\infty(0, +\infty; X)\), there exist \(\varepsilon > 0\) and \(z_n \in \Theta_{\Sigma(h_n)}\) such that

\[
(3.2) \quad \text{dist}(z_n, \Theta) \geq \varepsilon.
\]

From Theorem 2.5 we have that \(\Theta_{\Sigma(h)} \subset K\), where compact \(K\) depends on \(R_0\) (see estimation \((2.22)\)). Then

\[
z_n \in \Theta_{\Sigma(h_n)} \subset S_{\Sigma(h_n)}(t, 0, \Theta_{\Sigma(h_n)}) \subset S_{\Sigma(h_n)}(t, 0, K).
\]

Therefore, \(z_n = u_n(t) = S_{d_n}(t, 0, \xi_n)\), where \(\xi_n \to \xi\) in \(X\), \(\|d_n\|_+ \leq \|h_n\|_\infty \to 0\).

Then from Lemma 2.6

\[
(3.3) \quad u_n(t) \to u(t) = S_0(t, 0, \xi) \subset S_0(t, 0, B_0).
\]

Due to the uniform attraction we can choose \(t > 0\) such that

\[
\text{dist}_X(S_0(t, 0, B_0), \Theta) < \frac{\varepsilon}{2}.
\]

Then from \((3.3)\)

\[
(z_n \to u(t) \in O_\xi(\Theta),
\]

that is a contradiction with \((3.2)\). Theorem is proved. \(\square\)
