(Received September 20, 1978)

ABSTRACT. Modifications are proposed to the Davidenko-Broyden algorithm for the solution of a system of nonlinear equations. The aim of the modifications is to reduce the overall number of function evaluations by limiting the number of function evaluations for any one subproblem. To do this alterations are made to the strategy used in determining the subproblems to be solved. The modifications are compared with other methods for a wide range of test problems, and are shown to significantly reduce the number of function evaluations for the difficult problems. For the easier problems the modified method is equivalent to the Davidenko-Broyden algorithm.

KEY WORDS AND PHRASES. Davidenko-Broyden algorithm, Nonlinear equations, Numerical Solutions.

1. INTRODUCTION

This paper considers the solution of a system of \( n \) nonlinear equations with \( n \) unknowns \( \mathbf{x} = (x_1, x_2, \ldots, x_n)^T \), i.e. the system

\[
\mathbf{f}(\mathbf{x}) = 0
\]

An essential requirement of numerical techniques for solving such a system is the existence of an initial approximation to the solution. In general the closer the initial approximation is to the solution the easier this solution is to obtain.

Davidenko\cite{3} approached the problem of providing a good approximation to the solution of the above system by transforming the original problem into a sequence of subproblems. Although the solution of each of the subproblems involves the solution of a nonlinear equation system the aim of the Davidenko method is to provide a sufficiently good approximation to each to ensure the overall difficulty of the problem is reduced.

Davidenko proposes a specific embedding or continuation which has the form

\[
\mathbf{g}(\mathbf{x}, \theta) = \mathbf{f}(\mathbf{x}) - \theta \mathbf{f}_O
\]

where \( \mathbf{f}_O = \mathbf{f}(\mathbf{x}_O) \)

\( \theta \) is a scalar parameter and \( \mathbf{x}_O \) the initial approximation to the solution. The variation of the parameter \( \theta \) provides the subproblems. In particular when \( \theta = 0 \)

\[
\mathbf{g}(\mathbf{x}, 0) = \mathbf{f}(\mathbf{x})
\]

gives the original system and when \( \theta = 1 \) then \( \mathbf{x}_O \) is a solution of

\[
\mathbf{g}(\mathbf{x}, 1) = 0
\]

this provides the initial subproblem. We can now specify a sequence of subproblems by taking values of \( \theta \)

\[
1 = \theta_0 > \theta_1 > \theta_2 > \ldots > \theta_m = 0
\]

then the subproblems will be

\[
\mathbf{g}(\mathbf{x}, \theta_i) = 0 \quad ; \quad i = 1, 2, 3, \ldots, m
\]
The $\theta_i$ should be chosen sufficiently close to one another so that the solution of one subproblem provides a good initial approximation for the next.

The major problem with this method is to make an effective choice of the $\theta_i$ values which reduces the difficulty of the problem. Broyden\cite{2} has studied the combination of his quasi Newton method\cite{1} with the method of Davidenko, the quasi Newton method being used as the subproblem solver. In this paper Broyden suggested a specific method for choosing the $\theta_i$ values. Broyden chose $\theta_0 = 1$, $\theta_1 = .99$ and $\theta_2 = .98$ and fitted a quadratic approximation through the solution points of the latest three subproblems. Broyden obtains an estimate of the $\theta$ value required for the next subproblem by extrapolating for $\theta$ using the current quadratic approximation, the extent of the extrapolation being limited according to the local nonlinearity of the problem.

Broyden's\cite{2} numerical studies showed that a significant improvement was obtained for harder problems by using this modified Davidenko technique with the quasi Newton method. However examination of the Davidenko-Broyden algorithm shows that for a number of problems a comparatively large proportion of the function evaluations arise from the solution of one or two subproblems indicating a poor choice of $\theta$. The next section proposes modifications to the Davidenko-Broyden algorithm with the aim of reducing the number of function evaluations.

2. MODIFICATION OF THE CONTINUATION METHOD

The aim of the modification is to prevent the number of function evaluations for solving any subproblem becoming excessive. The Davidenko-Broyden continuation method, as discussed in the previous section, solves the sequence of subproblems

$$g(x, \theta_i) = 0 \quad i = 1, \ldots, m$$  \hspace{1cm} (2.1)

If in solving equation (2.1) for some $\theta_{r+1}$ the number of function
evaluations reaches a value MAXK without convergence to the solution, then it
suggests that the step from \( \Theta_r \) to \( \Theta_{r+1} \) is too large and the solution of
\[
g(x, \Theta_{r+1}) = 0
\]
should be terminated. We must now choose a revised \( \Theta \) for which convergence
may be obtained within MAXK iterations without wasting the effort expended in
part solving (2.2).

The strategy proposed here is to compute a new value, \( \Theta^* \), from \( x^* \), the
solution vector at the point of terminating the solution of (2.2). The sub-
problem \( g(x, \Theta^*) = 0 \) is then solved, \( x^* \) being used as the initial approximation.

If \( x^* \) is the solution vector of (2.2) after MAXK function evaluations, then
as this is not the exact solution we can write
\[
g(x^*, \Theta) = \varepsilon
\]

i.e.
\[
f(x^*) - \Theta f_0 = \varepsilon
\]

We wish to calculate a \( \Theta \) such that the error vector \( \varepsilon \) is as small as possible.
That is, choose \( \Theta \) so as to minimise
\[
S = \sum_{i=1}^{n} | | \varepsilon_i ||^2
\]
\[
= \sum_{i=1}^{n} (f_i(x^*) - \Theta f_i(x_0))^2
\]

Differentiating
\[
\frac{\partial S}{\partial \Theta} = -2 \sum_{i=1}^{n} f_i(x_0)(f_i(x^*) - \Theta f_i(x_0))
\]
\[
= -2(f_0^T \varepsilon^* - \Theta f_0^T \varepsilon_0)
\]
The second derivative \( \frac{\partial^2 S}{\partial \Theta^2} = 2f_0^T f_0 > 0 \), so that \( S \) is a minimum when \( \Theta \) has
the value \( \Theta^* = (f_0^T f_0)^{-1} f_0^T \varepsilon_0 \). Or, by writing \( f^* = g^* + \Theta_{r+1} f_0 \),
where \( g^* = g(x^*, \Theta_{r+1}) \),
\[
\Theta^* = \Theta_{r+1} + (f_0^T \varepsilon^*)/(f_0^T f_0)
\]
(2.4)
The $\theta^*$ computed from equation (2.4) may lie outside the range $[\theta_{r+1}, \theta_r]$. If this occurs then $\theta^*$ is set equal to $\theta_{r+1}$, i.e., we continue with the solution of (2.2). $\theta^*$ is also set equal $\theta_{r+1}$ if the following condition on the norm of $f(x^*)$ is not satisfied.

$$||f(x^*)|| < ||f(x_r)||$$  \hspace{1cm} (2.5)

If the condition (2.5) is satisfied then prior to the solving of the subproblem $g(x, \theta^*) = 0$ a new initial approximation to the inverse Jacobian used by Broyden quasi Newton method is computed. In other words the computed value of $\theta^*$ is only used if the solution vector $x^*$ is a better approximation to the solution of the nonlinear equations $f(x) = 0$ than $x_r$, the solution of the previous subproblem. If condition (2.5) is not satisfied or $\theta^*$ is out of range then we continue with the solution of (2.2) with $x^*$ as the starting vector for another MAXK function evaluation.

Once a solution of $g(x, \theta^*) = 0$ has been found we proceed in the normal way and compute the next $\theta$ from $\theta_{r-1}$, $\theta_r$ and $\theta^*$ and the solutions of the corresponding subproblems.

In solving the text problems in the next section the value for MAXK is chosen to be 25. This is an arbitrary choice and there may be some other optimal choice for this parameter, probably problem dependent. However Swift and Lindfield[6] performed experiments with different MAXK values for single nonlinear equations and found that within a range the value of MAXK was not critical.

3. RESULTS AND DISCUSSION

In this section the proposed modification is compared with the unmodified algorithm of Broyden[1] and the continuation method of Broyden[2].

Also considered is the algorithm of Powell[5]. This is a hybrid method using approximations to the Jacobian and inverse Jacobian to estimate a Newton step and
a step along the direction of steepest descent. The actual correction to the solution is a linear combination of these two steps. This algorithm is included as it is currently in the Mark 5 release of the Numerical Algorithms Group (NAG) Library.

The test equations are now presented. Test problems 1) – 3) are those of Broyden\[2\], problems 2) and 3) being particularly difficult. The algebraic equations 4) and 5) again prove difficult to solve; problem 6) is the test example appearing in the NAG specification of the Powell algorithm\[5\].

1) BROYDEN[2] EXAMPLE 3

\[
f_i = \sum_{j=1}^{6} \cot(x_j \beta_i) \quad j \neq i \quad i = 1, \ldots, 6
\]

\[10^2 \beta_1 = 2.249, 2.166, 2.083, 2.000, 1.918, 1.835\]

initial values \(x_1 = 75.0, i = 1, \ldots, 6\)

2) BROYDEN[2] EXAMPLE 6

\[
f_1 = 2(x_1 - 1) - 400x_1(x_2 - x_1^2)
\]

\[
f_2 = 200(x_2 - x_1^2)
\]

initial values \(x_1 = -1.2, x_2 = 1.0\)

3) BROYDEN[2] EXAMPLE 7

Equations as in 2), initial values \(x_1 = -1.0,\)

\[
x_2 = 1.0
\]

4) \[
f_1 = x_1 + x_2 + 2x_3 + 2
\]

\[
f_2 = x_1 x_2 + x_3^2 + x_4^2 + 2x_3(x_1 + x_2)
\]

\[
f_3 = 2x_1 x_2 x_3 + (x_1 + x_2)(x_3^2 + x_4^2) - 1
\]

\[
f_4 = x_1 x_2 (x_3^2 + x_4^2) + 2
\]
initial values $x_1 = 7.5$, $x_2 = 11.0$, $x_3 = 5.0$, $x_4 = 7.0$

5) $f_1 = -13 + x_1 + ((5-x_2)x_2 - 2)x_2$
   $f_2 = -29 + x_1 + ((1+x_2)x_2 - 14)x_2$

initial values $x_1 = 15.0$, $x_2 = -2.0$

6) $f_1 = x_1(1 - x_2^2) - 2.25$
   $f_2 = x_1(1 - x_2^3) - 2.625$

7) $f_1 = -400x_1(x_2 - x_1^2) - 2(1 - x_1)$
   $f_2 = 200(x_2 - x_1^2) + 20.2(x_2 - 1) + 19.8(x_4 - 1)$
   $f_3 = -360x_3(x_4 - x_3^2) + 2(1 - x_3)$
   $f_4 = 180(x_4 - x_3^2) + 20.2(x_4 - 1) + 19.8(x_2 - 1)$

initial values $x_1=0.5$, $x_2=1.5$, $x_3=1.5$, $x_4=0.5$

8) Equations as in 7)
   initial values $x_1=-1.2$, $x_2=1.0$, $x_3=1.0$, $x_4=2.0$

The results of testing the various algorithms on these problems are presented in Table I. For each method the figures given are the total number of times the equations are evaluated in solving a problem to the specified accuracy. In all cases no more than 500 function evaluations were permitted. The convergence criterion used is that $||f(x)|| < 10^{-9}$, or for the subproblems in the continuation algorithms $||g(x,0)|| < 10^{-9}$.

The abbreviations used for the different methods presented in Table I are that Broyden's unmodified algorithm given in section 2, with the parameter $t = 1$, is denoted by B. The Davidenko-Broyden method is denoted by DB. This method
also uses $t = 1$ and the results correspond to the method of Broyden[2] where an initial approximation to the inverse Jacobian is computed before the start of each subproblem. The NAG routine of Powell is denoted by P and the proposed modified Davidenko-Broyden algorithm by MDB.

Comparison of the first two columns in Table I shows that the unmodified version of Broyden's algorithm and the NAG routine of Powell are very similar in their performance. Powell's algorithm being superior for problems 6), 7) and 8), but inferior for problem 1). However, out of the eight test problems the NAG routine fails to produce solutions in five of them. The failures marked F in column P are not due to exceeding the maximum number of function evaluations but due to some other failure in the NAG routine.

The Davidenko-Broyden algorithm produces solutions to all but one of the problems. It fails for problem 7) but is very satisfactory for problem 8), which is the same problem but with different starting values. The DB algorithm tends to take more function evaluations than the Broyden algorithm for the easier problems, but is much better for the difficult problems.

The modified Davidenko-Broyden algorithm gives converged results for all the test problems. For the difficult problems 2), 4), 7) and 8), where the DB algorithm takes a large number of function evaluations, the modified method significantly reduces the number of function evaluations. For the easier problems it performs the same as the DB algorithm.

An examination of the sequence of $\theta$ values used by the Davidenko-Broyden algorithm in solving the four difficult problems, shows that only three subproblems are solved for $\theta$ values of 0.99, 0.98 and 0.0. In all cases the majority of function evaluations arise from the subproblem with $\theta = 0$, as shown in Table II.
The modified method however, stops the solution of the subproblem with \( \theta = 0 \) after MAXK function evaluations and calculates a \( \theta^* \) close to zero and solves the subproblems \( g(x, \theta^*) = 0 \) as is shown in Table III for problems 4) and 8).

The value of 30 function evaluations appearing after the first attempt to solve the subproblem with \( \theta = 0 \), comprises 25 evaluations (MAXK) from the solving of the subproblem and \( (n+1) \) function evaluations from the computation of the new initial approximation to the inverse Jacobian before solving the subproblem.

For problem 4) the \( \theta^* \) computed after the termination of the solution of \( g(x,0) = 0 \) is out of range and so the solution of the subproblem with \( \theta = 0 \) is continued after computing a new initial approximation to the inverse Jacobian. This is sufficient for convergence to be attained after another 13 function evaluations.

It can be seen therefore that the modifications to the Davidenko-Broyden algorithm have the desired effect of spreading out the function evaluations among the subproblems and in reducing the total number of function evaluations.

REFERENCES

Special Issue on
Time-Dependent Billiards

Call for Papers

This subject has been extensively studied in the past years for one-, two-, and three-dimensional space. Additionally, such dynamical systems can exhibit a very important and still unexplained phenomenon, called as the Fermi acceleration phenomenon. Basically, the phenomenon of Fermi acceleration (FA) is a process in which a classical particle can acquire unbounded energy from collisions with a heavy moving wall. This phenomenon was originally proposed by Enrico Fermi in 1949 as a possible explanation of the origin of the large energies of the cosmic particles. His original model was then modified and considered under different approaches and using many versions. Moreover, applications of FA have been of a large broad interest in many different fields of science including plasma physics, astrophysics, atomic physics, optics, and time-dependent billiard problems and they are useful for controlling chaos in Engineering and dynamical systems exhibiting chaos (both conservative and dissipative chaos).

We intend to publish in this special issue papers reporting research on time-dependent billiards. The topic includes both conservative and dissipative dynamics. Papers discussing dynamical properties, statistical and mathematical results, stability investigation of the phase space structure, the phenomenon of Fermi acceleration, conditions for having suppression of Fermi acceleration, and computational and numerical methods for exploring these structures and applications are welcome.

To be acceptable for publication in the special issue of Mathematical Problems in Engineering, papers must make significant, original, and correct contributions to one or more of the topics above mentioned. Mathematical papers regarding the topics above are also welcome.

Authors should follow the Mathematical Problems in Engineering manuscript format described at http://www.hindawi.com/journals/mpe/. Prospective authors should submit an electronic copy of their complete manuscript through the journal Manuscript Tracking System at http://mts.hindawi.com/ according to the following timetable:
