(Received March 20, 1996)

ABSTRACT: A linearized theory of magnetoatmospheric waves is developed where the restoring forces are those of compressibility and magnetic pressure. An equation for resonance is derived. Reflection and tunneling of upward propagating Alfvén waves in an ideal Magnetoatmosphere are considered. It is shown that the magnetic field produces a reflecting nonabsorbing critical layer. Below the critical layer, the solution of the problem can be written as a linear combination of an upward and a downward propagating wave and above it the solution decays exponentially with the altitude. The location of the critical layer and the magnitude of the reflection coefficient are determined and the conclusions are discussed in connection with the heating mechanism of the solar atmosphere.

KEY WORDS: Magnetoatmosphere, critical layer, wave propagation

1991 AMS SUBJECT CLASSIFICATION CODES: 76N, 76Q

1 INTRODUCTION

The dynamics of the solar atmosphere is complicated by the fact that not only is it strongly stratified, in both gas density and temperature, but it is also permeated by a non-uniform magnetic field. The solar atmosphere is an example of a plasma that is both structured and stratified. More specifically, the sun is a compressible plasma and able to support sound waves. The presence of a strong magnetic field indicates that the solar atmosphere is an elastic medium. Thus, wave motions of various types will occur and become a source of energy in the solar atmosphere.

In this paper a linearized theory of magnetoatmospheric waves, involving the combined restoring forces due to compressibility and magnetic pressure, is developed for the case of a uniform horizontal magnetic field. A general propagation equation is derived for adiabatic perturbations with arbitrary vertical distribution of Alfvén and sound speeds. An exact analytical solution of the propagation equation is obtained for the case of an isothermal atmosphere permeated by a uniform horizontal magnetic field. We examine the propagation of Alfvén waves in two distinct regions in the solar atmosphere, which is taken to be an ideal one. It is shown that in the first region, where the strength of the magnetic field is weak, the solution can be written as a linear combination of upward and downward propagating waves...
with equal wavelengths. In the first region the motion is approximately acoustic because the motion is dominated by the restoring force of compressibility. In the second region, where the magnetic field strength dominates the motion, the solution decays exponentially with altitude. The first and second regions are connected by a critical layer in which the reflection takes place and the motion is influenced greatly by the effect of the magnetic field. Also, the behavior of the solution, in both regions, indicates that the tunneling is weak as the waves, of all kinds, propagate between the two regions and the reflection is very strong. We expect the motion, in both regions to continue in its prescribed form because there is no physical mechanism for dissipation. The reflection coefficient, location of the transition region, critical layer, and the conclusions are presented in connection with the heating mechanism of the solar atmosphere.

Finally, in the formulation of the problem we will be able to introduce and justify the so-called "magnetic energy condition" in an ideal Magnetoatmosphere as an upper boundary condition to ensure a unique solution.

2 PROBLEM FORMULATION

We consider an ideal magnetoatmosphere which is inviscid and thermally non-conducting, and occupies the upper half-space \( z > 0 \). It is assumed that the gas is under the influence of a uniform horizontal magnetic field and that it has an infinite electrical conductivity. We investigate the problem of small vertical oscillations about equilibrium.

Let the equilibrium pressure, density, magnetic field intensity and external potential be denoted by \( P_0(z), \rho_0(z), B(z) \) and \( \psi_0(z) \). Let \( \rho, \rho, B, \psi \) and \( V \) be the perturbations in the pressure, density, magnetic field intensity, external potential and velocity. The equations of ideal magnetohydrodynamics are those of momentum, induction, isotropy, and continuity:

\[
\rho \left[ \frac{\partial V}{\partial t} + V \cdot V \right] = -\nabla P - B \times (\nabla \times B) - \rho \nabla \psi, \tag{2.1}
\]

\[
\frac{\partial B}{\partial t} = \nabla \times (V \times B), \tag{2.2}
\]

\[
\left[ \frac{\partial}{\partial t} + V \cdot V \right] \left( P \rho^{-\gamma} \right) = 0, \tag{2.3}
\]

\[
\left[ \frac{\partial}{\partial t} + V \cdot V \right] \rho = -\rho \nabla \cdot V. \tag{2.4}
\]

Here \( \gamma \) denotes the ratio of the specific heats. These equations are linearized about a static equilibrium defined by

\[
\nabla P_0 + B_0 \times (\nabla \times B_0) = -\rho_0 \nabla \psi_0. \tag{2.5}
\]

In this problem \( \psi_0 \) is considered to represent a uniform gravitational field. Thus, \( \nabla \psi_0 = -g = (0, 0, g) \) and the last term in equations (2.1) and (2.5) is replaced by \( \rho_0 g \). In terms of the linear Lagrangian displacement field \( \xi(r,t) \), the velocity perturbation is defined by:

\[
V = \frac{\partial \xi}{\partial t}, \tag{2.6}
\]

and the equation of motion of ideal magnetohydrodynamic is obtained by integrating and eliminating all perturbation quantities except \( \xi \). As a result, we have

\[
\rho_0 \frac{\partial^2 \xi}{\partial t^2} = F(\xi), \tag{2.7}
\]
where the force operator $F(\xi)$ is defined by

$$F(\xi) = \nabla (\gamma P_0 \nabla \cdot \xi + \xi \cdot \nabla P_0) - B_0 \times (\nabla \times R) - R \times (\nabla \times B_0) + \nabla \cdot (\rho_0 \xi) \nabla \psi_0,$$

where

$$R = \nabla \times (\xi \times B_0).$$

The linear Lagrangian displacement field is assumed to be of the form $\xi(x, y, z, t)$ and as an integral superposition of harmonic terms, with $\xi$ and its first $x$ derivative vanishing at infinity. As a result,

$$\xi = \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{-\text{i} k z} e^{\text{i} k \cdot \mathbf{x}} \, dk,$$

where the wave number is assumed to be $k = (k_x, 0, 0)$. Consequently, the horizontal magnetic field can be written as

$$B_0 = (B_0(x), B_y(x), 0).$$

Using equation (2.10), equation (2.7) becomes

$$-\rho_0 \omega^2 \phi = F(\phi, k).$$

Eliminating all variables except $\phi_x$, we obtain the following differential equation:

$$\frac{d}{dz} \left[ A(z, \omega) \frac{d\phi_x}{dz} \right] + C(z, \omega) \phi = 0,$$

where the coefficient $A(z, \omega)$ and $C(z, \omega)$ have the following form:

$$A(z, \omega) = \frac{\rho_0 A_{11} A_{12} A_{13}}{A_{14} A_{15}},$$

$$C(z, \omega) = \rho_0 \left[ A_{12} - \frac{k^2 g^2 A_{12}}{A_{14} A_{15}} - \frac{k^2 g}{A_{11} - A_{17}} \left( \frac{d}{dz} \left[ \rho_0 \left( \frac{A_{11} - A_{17}}{A_{14} A_{15}} \right) A_{16} \right] \right) \right],$$

where

$$A_{11} = a_x^2 + a_y^2 + c_0^2, \quad A_{12} = \omega^2 - a_x^2 k^2,$$

$$A_{13} = \omega^2 - \frac{a_x^2 k^2}{A_{11} - a_y}, \quad A_{14} = \omega^2 - \frac{1}{2} \left[ k^2 A_{11} - A_{17} \right],$$

$$A_{15} = \omega - \frac{1}{2} \left[ k^2 A_{11} + A_{17} \right], \quad A_{16} = \omega - \frac{a_x c_0^2 k^2}{A_{11} - a_x},$$

$$A_{17} = k^4 \left[ A_{11}^2 - 4 a_x^2 c_0^2 \right].$$

The parameters $a_x$ and $a_y$ are the $x$ and $y$ components of Alfven speed, while $c_0$ denotes the speed of sound.

### 3 SIMPLIFICATION OF THE PROBLEM AND BOUNDARY CONDITIONS

For this problem the atmosphere is assumed to be isothermal ($c_0 = c(z)$ = constant) and permeated by a uniform horizontal magnetic field $B = (B, 0, 0)$. The equilibrium pressure $P_0$ and constant temperature $T_0$ satisfy the gas law $P_0 = RT_0 \rho_0$ and the hydrostatic equation $P_0'(z) + g \rho_0 = 0$. Here, $R$ denotes the gas constant and the prime denotes differentiation with respect to $z$. As a result, the equilibrium pressure and density can be written as:

$$P_0(z) = P_0(0) \exp(-z/H), \quad \rho_0(z) = \rho_0(0) \exp(-z/H),$$

where $P_0(0)$ and $\rho_0(0)$ are the pressure and density at the lower boundary of the atmosphere, respectively.
where \( H = -\rho_0 (z) / \rho_0 (z) = \frac{M a}{g} \) is the density scale height. Consequently, the differential equation (2.13) becomes

\[
\omega^2 c^2 + \left( \omega^2 - c^2 k^2 \right) \alpha^2 (0) \exp \left( \frac{z}{H} \right) \phi ^{\prime \prime} (z) - \frac{c^2 \omega^2}{H} \phi ^{\prime} (z) + \\
\left[ \omega^2 - c^2 k^2 \right] \left( \omega^2 - k^2 \alpha^2 (0) \exp \left( \frac{z}{H} \right) - \frac{g}{H} \left( \frac{c^2}{H} \right) \phi (z) = 0, \right.
\]

(3.2)

where

\[
\alpha^2 (0) = \frac{B^2}{4 \pi \rho_0 (0)},
\]

denotes Alfvén speed at \( z = 0 \). Furthermore, we introduce the following dimensionless quantities and variables:

\[
\phi (z) = \frac{W (z)}{w}, \quad x = x_0 \exp \left( \frac{z}{H} \right), \quad \dot{z} = \frac{z}{H}, \quad k = He, \quad x_0 = \frac{\beta^2 \sigma^2}{k^2 - \sigma^2}, \quad \beta^2 = \frac{\alpha^2 (0)}{c^2}, \quad \gamma = \frac{H \omega}{c},
\]

(3.3)

(3.4)

(3.5)

where the prime on \( z \) is eliminated for simplicity. Thus, the differential equation (3.2) becomes,

\[
x (1 - x) \frac{d^2 W (x)}{dx^2} + \left( c - (a + b + 1) x \right) \frac{dW (x)}{dx} - ab W (x) = 0.
\]

(3.6)

It is clear that the differential equation (3.5) is a special case of the hypergeometric differential equation with

\[
a + b = c = 2k + 1, \quad ab = \sigma^2 + k + \left( \frac{1}{\gamma} \right) \frac{k^2}{\sigma^2},
\]

(3.7)

Boundary Conditions:

To complete the formulation of the problem, certain conditions must be imposed to ensure a unique solution. If the atmosphere is viscous, an appropriate condition would be the dissipation condition, which requires the finiteness of the rate of the energy dissipation in an infinite column of fluid of unit cross-section. Since the dissipation function depends on the squares of the velocity gradients, this implies

\[
\int_0^\infty |W|^2 \, dx < \infty.
\]

(3.8)

In our problem the atmosphere is not viscous, but the integral in (3.7) is proportional to the magnetic energy in an infinite column of fluid. This condition is a reasonable one to apply so long as there is no energy radiation to infinity, which is true in our case, and we shall call this condition "magnetic energy condition." Thus we will require (3.7) even when the atmosphere is inviscid. A boundary condition is also required at \( x = 0 \), and we shall set

\[
W (0) = 1,
\]

(3.9)

by suitably normalizing \( W (x) \). It will be seen that the boundary conditions (3.7) and (3.8) will determine a unique solution to within a multiplicative constant.

4 SOLUTION OF THE PROBLEM

In this section we investigate solutions of the following differential equation,

\[
x (1 - x) \frac{d^2 W (x)}{dx^2} + \left[ c - (a + b + 1) x \right] \frac{dW (x)}{dx} - ab W (x) = 0.
\]

(4.1)

where

\[
a + b = c = 2k + 1, \quad ab = \sigma^2 + k + \left( \frac{1}{\gamma} \right) \frac{k^2}{\sigma^2},
\]

(4.2)
subject to the prescribed boundary conditions. Solving for the parameters $a$ and $b$, we obtain

$$a = \frac{1}{2} + k - r, \quad b = \frac{1}{2} + k + r,$$

where

$$r = \sqrt{r_1 - r_2}, \quad r_1 = \frac{1}{4} + k^2 \quad \text{and} \quad r_2 = \sigma^2 + \frac{\gamma - 1}{\gamma} \frac{k^2}{\sigma^2}.$$  

It is clear that the parameter $r$ is a real number, for $r_1 > r_2$, $r = 0$ for $r_1 = r_2$ and $r = i\sqrt{r_2 - r_1}$ for $r_1 < r_2$. The differential equation (4.1) is a special case of the hypergeometric equation which has three regular singular points at $x = 0$, $x = 1$ and $x = \infty$. The intermediate regular singular point, $x = 1$, corresponds to the existence of the critical layer, which has a great importance for understanding the heating mechanism of the solar atmosphere. As a result, the differential equation (4.1) has two linearly independent solutions which can be written in the following form for $|x| < 1$.

$$W_1(x) = F(a, b; c; x),$$

$$W_2(x) = x^{1-c} F(a + 1, b - c + 1; 2 - c; x),$$

$$F(a, b; c; x) = \frac{\Gamma(c)}{\Gamma(a) \Gamma(b)} \sum_{n=0}^{\infty} \frac{\Gamma(a + n) \Gamma(b + n)}{\Gamma(c + n)} \frac{x^n}{n!}.$$  

Since $k > 0$, then $1 - c = -2k < 0$, and

$$x^{1-c} = [x_0 \exp(-z)]^{1-c} \to \infty, \text{ as } z \to \infty.$$  

Thus, the solution of the differential equation (4.1) as defined by equation (4.5) will be eliminated by the magnetic energy condition. Consequently, the general solution of the differential equation (4.1) is

$$W(x) = A F(a, b; c; x),$$

where $A$ is an arbitrary constant and can be determined by the boundary condition (3.8). Using the asymptotic behavior of $F(a, b; c; x)$ for $|x| > 1$ and reintroducing the variable $z$, the solution of (4.4) can be written as

$$W(z) = \text{Cons} \cdot \left[ \exp \left( \frac{1}{2} + k + i\theta \right) R \exp \left( \frac{1}{2} + k - i\theta \right) \right],$$

where $R$ denotes the reflection coefficient and defined by

$$R = \exp [i (\theta + 2\pi \log x_0)],$$

and

$$\theta = \arg(R) = \arg \left[ \frac{\Gamma(a) \Gamma(b-a) \Gamma(c-b)}{\Gamma(a-b) \Gamma(b) \Gamma(c-a)} \right].$$

5 GENERAL DISCUSSION

The structured nature of the solar magnetic field means that magnetism is of greater importance in some regions of the sun than in others. A simple guide to the relative importance of magnetic effects is provided by the plasma beta, $\beta$, defined by

$$\beta = \frac{P_0}{P_m} = \frac{2}{\gamma} \left( \frac{c}{\alpha} \right)^2,$$  

where $P_0$ and $P_m$ are the total plasma and magnetic pressures, respectively. A number of physical situations are described in the literature of solar physics.
where $P_m$ denotes the magnetic pressure. A low-$\beta$ plasma, such as the corona, is thus one for which the Alfvén speed greatly exceeds the sound speed, $\alpha \gg c$. Wave propagation, then, involves the two speeds $c$ and $\alpha$. In fact, the sound speed exists and inter into a description of propagation speeds only in the combination with Alfvén speed. As a result, the wave speed $W_s$ is such, $S_s < W_s < F_s$, where $F_s$ and $S_s$ are the fast and slow speeds and defined by

$$F_s^2 = c^2 + \alpha^2, \quad S_s^2 = c^{-2} + \alpha^{-2}. \quad (5.2)$$

Moreover, $F_s$ will be refered to as magnetoacoustic speed; it is super-sonic and super-Alfvénic. By contrast, $S_s$ is both sub-sonic and sub-Alfvénic.

It is easy to see that the maximum of the kinetic energy $\text{Max}(K) \propto 1$. As a result, when the reflection coefficient $R \rightarrow -1$, we have $\text{Max}(K) \rightarrow \infty$. This occures when

$$\theta + 2r \log z_0 = (2n + 1) \pi. \quad (5.3)$$

We call this equation, resonance equation.

From the above discussion and the asymptotic behavior of the solution, expressed in (4.9), we have the following observations:

(A) It is clear that $|R| = 1$. As a result, the magnetic field produces a nonabsorbing critical layer, below it the solution can be written as a linear combination of an upward and a downward propagating wave with the same wavelengths. Above the critical layer the solution decays exponentially with altitude. Thus, the critical layer separates two distinct regions with different physical properties.

(B) In the critical layer the reflection and the wave modification take place. Since $|R| = 1$, the tunneling is very weak while the reflection is very strong. In this case the total energy of the wave is divided equally between the incident and reflected waves.

(C) Since the Magnetosatmosphere is ideal, there is a physical mechanism for dissipation. Thus, we expect the motion to continue in this form and become one of the main sources of energy in the solar atmosphere.

(D) As a result of (B) and (C) we see that the heating process is an acoustic one below the critical layer because the compressibility force dominates the oscillatory process. As we move from a region of weak magnetic field to another one with a strong magnetic field, the heating process becomes magnetoacoustic.

Special Issue on
Time-Dependent Billiards

Call for Papers

This subject has been extensively studied in the past years for one-, two-, and three-dimensional space. Additionally, such dynamical systems can exhibit a very important and still unexplained phenomenon, called the Fermi acceleration phenomenon. Basically, the phenomenon of Fermi acceleration (FA) is a process in which a classical particle can acquire unbounded energy from collisions with a heavy moving wall. This phenomenon was originally proposed by Enrico Fermi in 1949 as a possible explanation of the origin of the large energies of the cosmic particles. His original model was then modified and considered under different approaches and using many versions. Moreover, applications of FA have been of a large broad interest in many different fields of science including plasma physics, astrophysics, atomic physics, optics, and time-dependent billiard problems and they are useful for controlling chaos in Engineering and dynamical systems exhibiting chaos (both conservative and dissipative chaos).

We intend to publish in this special issue papers reporting research on time-dependent billiards. The topic includes both conservative and dissipative dynamics. Papers discussing dynamical properties, statistical and mathematical results, stability investigation of the phase space structure, the phenomenon of Fermi acceleration, conditions for having suppression of Fermi acceleration, and computational and numerical methods for exploring these structures and applications are welcome.

To be acceptable for publication in the special issue of Mathematical Problems in Engineering, papers must make significant, original, and correct contributions to one or more of the topics above mentioned. Mathematical papers regarding the topics above are also welcome.

Authors should follow the Mathematical Problems in Engineering manuscript format described at http://www.hindawi.com/journals/mpe/. Prospective authors should submit an electronic copy of their complete manuscript through the journal Manuscript Tracking System at http://mts.hindawi.com/ according to the following timetable:
