

# A NOTE ON ARITHMETIC PROGRESSIONS ON ELLIPTIC CURVES 

Garikai Campbell<br>Department of Mathematics and Statistics<br>Swarthmore College<br>Swarthmore, PA 19081<br>USA

#### Abstract

Andrew Bremner (Experiment. Math. 8 (1999), 409-413) has described a technique for producing infinite families of elliptic curves containing length 7 and length 8 arithmetic progressions. This note describes another way to produce infinite families of elliptic curves containing length 7 and length 8 arithmetic progressions. We illustrate how the technique articulated here gives an easy way to produce an elliptic curve containing a length 12 progression and an infinite family of elliptic curves containing a length 9 progression, with the caveat that these curves are not in Weierstrass form.

## 1. Introduction.

There are two (affine) models of elliptic curve that are very common. They are $y^{2}=f(x)$ where $f(x)$ is either a cubic or a quartic. We will say that points on a particular model of an elliptic curve are in arithmetic progression if their $x$-coordinates form an arithmetic progression. For example, Buhler, Gross and Zagier [3] found that the points $(-3,0),(-2,3)$, $(-1,3),(0,2),(1,0),(2,0),(3,3)$, and $(4,6)$ form an arithmetic progression of length 8 on the curve $y^{2}+y=(x-1)(x-2)(x+3)$. Moreover, Bremner [2] proves:

Theorem 1.1. Each point on the elliptic curve

$$
C: y^{2}=x^{3}-x^{2}-36 x+36
$$

corresponds to an elliptic curve in Weierstrass form containing at least 8 points in arithmetic progression.

Before proving this theorem, Bremner considers the following strategy. First he remarks that any monic degree 8 polynomial, $P(x)$, can be written as $Q(x)^{2}-R(x)$ where the degree of $R(x)$ is less than or equal to 3 . If $R(x)$ has degree precisely 3 and no repeated zeros, then $y^{2}=R(x)$ is an elliptic curve and for each zero, $\alpha$, of $P(x)$, this elliptic curve contains a pair of points with $x$-coordinate $\alpha$. So one possible strategy for producing an elliptic curve with an arithmetic progression of length 8 might be to let $P(x)=x(x+1)(x+2) \cdots(x+7)$ and compute the corresponding $R(x)$ so that $P(x)=Q(x)^{2}-R(x)$. Unfortunately, in this case, $R(x)$ is linear and so this strategy fails for any degree 8 polynomial whose zeros form an arithmetic progression. The goal of this note is to illustrate how to turn this strategy into a successful one.

## 2. Arithmetic Progressions of Length 8

The statement that a degree 8 polynomial can be written as $Q(x)^{2}-P(x)$ is a special case of the following:

Proposition 2.1. If $P(x)$ is a monic polynomial of degree $2 n$ defined over a field $k$, then there are unique polynomials $Q(x)$ and $R(x)$ defined over $k$ such that
(1) $P(x)=Q(x)^{2}-R(x)$ and
(2) the degree of $R(x)$ is strictly less than $n$.

Since $R(x)$ is a square at every zero of $P(x)$, if $R(x)$ is a cubic or a quartic with no repeated zeros, then we can produce elliptic curves $y^{2}=R(x)$ with great control over many of the $x$-coordinates.

Remark 2.2. We note that Mestre [9] was first to observe that this relatively simple proposition could be used to produce elliptic curves of large rank. Since Mestre's first paper exploiting this idea, many others ([0], [6], [7], 8], [1]) have used the proposition in clever ways to produce elliptic curves and infinite families of elliptic curves with the largest known rank (often with some condition on the torsion subgroup).

Now consider the polynomial

$$
p_{t}(x)=(x-t)^{2} \prod_{j=0}^{5}(x-j) \in \mathbb{Q}(t)[x]
$$

In this case, we can write

$$
p_{t}(x)=q_{t}(x)^{2}-f_{t}(x),
$$

where $f_{t}(x)$ is a polynomial of degree 3 in $\mathbb{Q}(t)[x]$ such that
(1) the discriminant of $f_{t}(x)$ is an irreducible polynomial in $\mathbb{Q}[t]$
(2) the coefficient of $x^{3}$ is $c(2 t-5)$, where $c \in \mathbb{Q}$.

Therefore, we have that
Theorem 2.3. The curve $E_{t}$ defined by $y^{2}=f_{t}(x)$ is an elliptic curve defined over $\mathbb{Q}(t)$, containing at least six points in arithmetic progression and for each $t_{0} \in \mathbb{Q}, t_{0} \neq 5 / 2$, the specialization of $E_{t}$ at $t=t_{0}$ gives an elliptic curve defined over $\mathbb{Q}$ containing at least six points in arithmetic progression.

We next observe that $f_{t}(6)$ is a conic in $\mathbb{Q}[t]$ which is a rational square when $t=6$. Therefore, we can parameterize all rational solutions to $y^{2}=f_{t}(6)$ by letting

$$
\begin{equation*}
t=\frac{6 m^{2}-126 m-285360}{m^{2}-72256} \tag{2.1}
\end{equation*}
$$

Since no rational value of $m$ gives $t=5 / 2$, we have:
Corrolary 2.4. Let $g_{m}(x)$ be the polynomial $f_{t}(x)$ with $t$ given by (2.1). The curve $E_{m}$ defined by $y^{2}=g_{m}(x)$ is an elliptic curve defined over $\mathbb{Q}(m)$ containing at least seven points in arithmetic progression and for each $m_{0} \in \mathbb{Q}$, the specialization of $E_{m}$ at $m=m_{0}$ gives an elliptic curve defined over $\mathbb{Q}$ containing at least seven points in arithmetic progression.

If we continue in this vein and explore the conditions imposed by $y^{2}=g_{m}(7)$, we find the following.

Theorem 2.5. Let $D$ be the elliptic curve defined by

$$
\begin{array}{r}
D: y^{2}=-264815 m^{4}-19343520 m^{3}+62846856064 m^{2} \\
-2906312951808 m-495507443511296 .
\end{array}
$$

Let

$$
\begin{aligned}
& g_{3}=-18816 m^{4}+677376 m^{3}+1922543616 m^{2} \\
& -48944480256 m-40678301368320 \text {, } \\
& g_{2}=236896 m^{4}-9821952 m^{3}-22598349824 m^{2} \\
& +508953231360 m+520252184657920, \\
& g_{1}=-958800 m^{4}+40985280 m^{3}+89932669440 m^{2} \\
& -1957723729920 m-2113363439616000 \text {, and } \\
& g_{0}=1292769 m^{4}-57304800 m^{3}-118795148928 m^{2} \\
& +2647001548800 m+2758336954896384 .
\end{aligned}
$$

Then

$$
E_{m}^{\prime}: y^{2}=g_{3} x^{3}+g_{2} x^{2}+g_{1} x+g_{0},
$$

is an elliptic curve defined over $\mathbb{Q}(D)$ containing the 8 points in arithmetic progression with $x$-coordinates 0, 1, 2, .., 7.

Proof. $E_{m}^{\prime}$ is isomorphic to $E_{m}$ via the change of variables $y \mapsto y /\left(m^{2}-72256\right)$. Substituting $x=7$ into $E_{m}^{\prime}$, we get the curve $D$.

Moreover, if we let $D(\mathbb{Q})$ be the group of rational points on $D$, then we have that $D(\mathbb{Q})$ is infinite. More specifically, we have:

Proposition 2.6. $D$ has rank 2 and torsion subgroup $\mathbb{Z} / 2 \mathbb{Z}$.
Proof. A short computer search reveals that $O=(-88,15628032)$ is a point in $D(\mathbb{Q})$. Taking $O$ taken to be the identity, $D(\mathbb{Q})$ is generated by

$$
\begin{aligned}
& P_{0}=(10984 / 79,-80015523840 / 6241) \text { and } \\
& P_{1}=(-1363640 / 2531,31969540657152 / 6405961)
\end{aligned}
$$

and contains the point of order two:

$$
P_{2}=(10984 / 79,80015523840 / 6241) .
$$

(The calculations above were performed with the help of mwrank [5] and GP [1].) An immediate consequence of the proposition above is the following:

Corrolary 2.7. Each point on the elliptic curve D corresponds to an elliptic curve in Weierstrass form containing at least 8 points in arithmetic progression.

Remark 2.8. This condition is very similar to the condition found in Bremner's constructionnamely, that points on the curve $C$ give rise to elliptic curves with 8 points in arithmetic progression. The differences are that $C$ has rank 1 and torsion subgroup $\mathbb{Z} / 2 \mathbb{Z} \times \mathbb{Z} / 2 \mathbb{Z}$, while $D$ has rank 2 and torsion subgroup $\mathbb{Z} / 2 \mathbb{Z}$.

## 3. Longer Progressions

This construction can also be used to produce progressions of length greater than 8 on elliptic curves of the form $y^{2}=f(x)$ where $f(x)$ is a quartic. More specifically, we have:

Theorem 3.1. There exists an elliptic curve in the form $y^{2}=w(x)$, with $w(x)$ a quartic, containing 12 points in arithmetic progression.

Proof. Let

$$
g_{0}(x)=\prod_{j=0}^{11}(x-j)
$$

Then $g_{0}(x)=u_{0}(x)^{2}-(81 / 4) \cdot v_{0}(x)$, with

$$
\begin{aligned}
u_{0}(x)= & x^{6}-33 x^{5}+418 x^{4}-2541 x^{3}+(14993 / 2) x^{2} \\
& -(18513 / 2) x+(4851 / 2), \text { and } \\
v_{0}(x)= & 429 x^{4}-9438 x^{3}+74295 x^{2}-246246 x+290521 .
\end{aligned}
$$

Since the discriminant of $v_{0}(x)$ is nonzero, the curve $E: y^{2}=v_{0}(x)$ is an elliptic curve. This elliptic curve then contains a length 12 arithmetic progression.
(Note that by using mwrank, we computed the rank of this curve to be 4 with torsion subgroup $\mathbb{Z} / 2 \mathbb{Z}$.)

The construction above produces a single curve and it is unclear how to produce an infinite family of curves containing a length 12 progression using this idea. The problem is that, in general, if the $P(x)$ of proposition 2.1 is taken to have degree 12 , then the $R(x)$ is only guaranteed to have degree less than or equal to 5 , not 4 . Therefore, the curve $y^{2}=R(x)$ need not be an elliptic curve. We can, however, prove the following.

Theorem 3.2. There are infinitely many elliptic curves of the form $y^{2}=w(x)$, with $w(x)$ a quartic, containing 9 points in arithmetic progression.

Proof. Let

$$
g(x)=(x-a) \cdot \prod_{j=0}^{8}(x-j)
$$

and write $g(x)$ as $u(x)^{2}-v(x) . v(x)$ is a degree four polynomial in $\mathbb{Q}(a)[x]$ with discriminant zero only for $a \in\{0,4,8\}$.

The work here (and that of Bremner) leaves open the following questions:
Open Question 3.3. Is there an elliptic curve of the form $y^{2}=f(x), f(x)$ a cubic, containing a length 9 arithmetic progression? Are there infinitely many?

Open Question 3.4. Is there an elliptic curve of the form $y^{2}=f(x), f(x)$ a quartic, containing a length 13 arithmetic progression? Are there infinitely many curves in this form containing a length 10 progression?

And finally,
Open Question 3.5. What is the longest arithmetic progression one can find on an elliptic curve in the form $y^{2}=f(x)$, where $f(x)$ is a cubic? a quartic?
