1. Introduction

# Injectivity of the Double Fibration Transform for Cycle Spaces of Flag Domains

Alan T. Huckleberry<sup>1</sup> and Joseph A. Wolf <sup>2</sup>

Communicated by K.-H. Neeb

Abstract. The basic setup consists of a complex flag manifold Z = G/Qwhere G is a complex semisimple Lie group and Q is a parabolic subgroup, an open orbit  $D = G_0(z) \subset Z$  where  $G_0$  is a real form of G, and a  $G_0$ homogeneous holomorphic vector bundle  $\mathbb{E} \to D$ . The topic here is the double fibration transform  $\mathcal{P} : H^q(D; \mathcal{O}(\mathbb{E})) \to H^0(\mathcal{M}_D; \mathcal{O}(\mathbb{E}'))$  where q is given by the geometry of D,  $\mathcal{M}_D$  is the cycle space of D, and  $\mathbb{E}' \to \mathcal{M}_D$  is a certain naturally derived holomorphic vector bundle. Schubert intersection theory is used to show that  $\mathcal{P}$  is injective whenever  $\mathbb{E}$  is sufficiently negative.

to each of its (finitely many) orbits. In this note we restrict to the case of an open orbit  $D = G_0(z_0)$ , and we often refer to such open orbits as flag domains.

The simplest example of this situation, where  $G_0 = SU(1,1)$ ,  $G = SL_2(\mathbb{C})$ and  $Z = \mathbb{P}_1(\mathbb{C})$ , is at first sight perhaps somewhat misleading. In this case D is either the set of of negative or positive lines and therefore is biholomorphic to the unit disk  $\Delta = \{z \in \mathbb{C} : |z| < 1\}$ . The naturally associated  $G_0$ -representations can be regarded as being in  $L^2$ -spaces of holomorphic functions on  $\mathcal{O}(\Delta)$ , or their complex conjugates.

Unless  $G_0$  is of Hermitian type and D is biholomorphically equivalent to the associated bounded symmetric domain as in the above example, the holomorphic functions do not separate the points of D; in fact in most cases  $\mathcal{O}(D) \cong \mathbb{C}$ . One explanation for this is that D generally contains positive-dimensional compact analytic subsets which are in fact closely related to the representation theory at hand. These arise initially as orbits of maximal compact subgroups  $K_0$  of  $G_0$ : There is a unique complex  $K_0$ -orbit  $C_0$  in D [20].

Of course  $C_0$  can be just a point, which is exactly the case when D is a bounded Hermitian symmetric domain, but in general it has positive dimension.

For example, if  $G_0 = SL_3(\mathbb{R})$ ,  $G = SL_3(\mathbb{C})$  and  $Z = \mathbb{P}_2(\mathbb{C})$ , then the closed  $G_0$ -orbit in Z is the set of real points  $Z_{\mathbb{R}} = \mathbb{P}_2(\mathbb{R})$  and its complement  $D = Z \setminus Z_{\mathbb{R}}$  is the only other orbit. If  $K_0$  is chosen to be the real orthogonal group  $K_0 = SO_3(\mathbb{R})$ , then

$$C_0 = \{ [z_0 : z_1 : z_2] : z_0^2 + z_1^2 + z_2^2 = 0 \}$$

is the standard quadric. Here one easily checks that  $\mathcal{O}(D) \cong \mathbb{C}$  and, in view of basic results of Andreotti and Grauert [2], looks for  $G_0$ -representations in Dolbeault cohomology  $H^1(D, \mathbb{E})$ , where  $\mathbb{E} \to D$  is a sufficiently negative holomorphic vector bundle.

Cohomology classes, e.g., classes of bundle valued differential forms, are technically and psychologically more difficult to handle than holomorphic functions or sections of vector bundles. Thus, for  $q := \dim_{\mathbb{C}} C_0$  one is led to consider the space  $\mathcal{C}^q(D)$  of q-dimensional cycles in D, where  $C_0$  can be considered as a point.

An element  $C \in C^q(D)$  is a linear combination,  $C = n_1C_1 + \ldots n_mC_m$ , with  $n_j \in \mathbb{N}^{>0}$  and where  $C_j$  is a *q*-dimensional irreducible compact analytic subset of D. It is also necessary to consider  $C^q(Z)$ , where the  $C_j$  are not required to be contained in D.

The cycle space  $C^q(X)$  of a complex space X has a canonical structure of (locally) finite-dimensional complex space (see [4] and, e.g., [14], for this and other basic properties). In the case at hand, where Z is projective algebraic,  $C^q(Z)$  is often referred to as the Chow variety; in particular, its irreducible components are projective algebraic varieties.

To simplify the notation we redefine  $C^q(Z)$  to be the topological component containing the base cycle  $C_0$ . It contains  $C^q(D)$  as an open semialgebraic subset. This is well defined independent of the choice of the maximal compact subgroup  $K_0$ .

It is known that the induced action of G on  $\mathcal{C}^q(Z)$  is algebraic (see, e.g., [15] for a detailed proof) and therefore the orbit  $\mathcal{M}_Z := G.C_0$  is Zariski open in its closure X in  $\mathcal{C}^q(Z)$ . It should be noted that  $\mathcal{M}_Z$  is a spherical homogeneous space

of the reductive group G and therefore the Luna–Vust theory of compactifications [5] applies. It would be extremely interesting to determine the G-varieties X which occur in this way.

In general it may be difficult to understand the full cycle space  $C^q(D)$  and therefore one cuts down to a simpler space which is more closely related to the group actions at hand. That simpler space is

 $\mathcal{M}_D$ : topological component of  $C_0$  in  $\mathcal{M}_Z \cap \mathcal{C}^q(D)$ .

We have the incidence space

$$\mathfrak{X}_D = \{ (z, C) \in D \times \mathcal{M}_D : z \in C \}.$$

and the projections  $\mu : \mathfrak{X}_D \to D$  defined by  $(z, C) \mapsto z$ , and  $\nu : \mathfrak{X}_D \to \mathcal{M}_D$  defined by  $(z, C) \mapsto C$ .

If  $\mathbb{E} \to D$  is a holomorphic vector bundle, we may lift it to  $\mu^*\mathbb{E} \to \mathfrak{X}_D$ consider the associated  $\nu$ -direct image sheaves on  $\mathcal{M}_D$ . In this way Dolbeault cohomology spaces  $H^q(D, \mathbb{E})$  are transformed to the level of sections of holomorphic vector bundles  $\mathbb{E}' \to \mathcal{M}_D$ . This *double fibration transform* is explained in detail in the next section. Since  $\mathcal{M}_D$  is now known to be a Stein domain ([21], [17]), our somewhat technical initial setting is transformed to one that is more tractable.

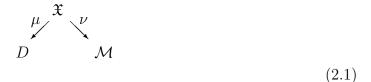

In recent work we developed complex geometric methods aimed at describing the cycle spaces  $\mathcal{M}_D$ . For example, for a fixed real form, the space  $\mathcal{M}_D$  is essentially always biholomorphically equivalent to a universal domain  $\mathcal{U}$  which is defined independent of D and Z ([17], [10]).

On the other hand, here we prove that  $\mathcal{M}_D$  possesses canonically defined holomorphic fibrations which do indeed depend on D and Z and which give it interesting refined structure. As a consequence we in particular show that the double fibration transform is injective, a fact that should be useful for representation theoretic considerations.

The present paper is organized as follows. In §2 we recall the basics of the double fibration transformation. The recently proved results of [17] and [10] are summarized in §3 and in §4 we give details on the method of Schubert slices. In the final section these slices are used to define the fibrations of  $\mathcal{M}_D$  which were mentioned above. The injectivity of the double fibration transform is a consequence of the topological triviality of these bundles.

# 2. Basics of the Double Fibration Transform

Let D be a complex manifold (later it will be an open orbit of a real reductive group  $G_0$  on a complex flag manifold Z = G/Q of its complexification ). We suppose that D fits into what we loosely call a holomorphic double fibration. This means that there are complex manifolds  $\mathcal{M}$  and  $\mathfrak{X}$  with maps

where  $\mu$  is a holomorphic submersion and  $\nu$  is a proper holomorphic map which is a locally trivial bundle. Given a locally free coherent analytic sheaf  $\mathcal{E} \to D$  we construct a locally free coherent analytic sheaf  $\mathcal{E}' \to \mathcal{M}$  and a transform

$$\mathcal{P}: H^q(D; \mathcal{E}) \to H^0(\mathcal{M}; \mathcal{E}')$$
(2.2)

under mild conditions on (2.1). This construction is fairly standard, but we need several results specific to the case of flag domains.

## Pull-back.

The first step is to pull cohomology back from D to  $\mathfrak{X}$ . Let  $\mu^{-1}(\mathcal{E}) \to \mathfrak{X}$ denote the inverse image sheaf. For every integer  $r \geq 0$  there is a natural map

$$\mu^{(r)}: H^r(D; \mathcal{E}) \to H^r(\mathfrak{X}; \mu^{-1}(\mathcal{E}))$$
(2.3)

given on the Čech cocycle level by  $\mu^{(r)}(c)(\sigma) = c(\mu(\sigma))$  where  $c \in Z^r(D; \mathcal{E})$  and where  $\sigma = (w_0, \ldots, w_r)$  is a simplex. For  $q \ge 0$  we consider the Buchdahl qcondition on the fiber F of  $\mu : \mathfrak{X} \to D$ :

$$F$$
 is connected and  $H^r(F; \mathbb{C}) = 0$  for  $1 \leq r \leq q - 1$ . (2.4)

**Proposition 2.5.** (See [6].) Fix  $q \ge 0$ . If (2.4) holds, then (2.3) is an isomorphism for  $r \le q - 1$  and is injective for r = q. If the fibers of  $\mu$  are cohomologically acyclic then (2.3) is an isomorphism for all r.

As usual,  $\mathcal{O}_X \to X$  denotes the structure sheaf of a complex manifold X and  $\mathcal{O}(\mathbb{E}) \to X$  denotes the sheaf of germs of holomorphic sections of a holomorphic vector bundle  $\mathbb{E} \to X$ . Let  $\mu^*(\mathcal{E}) := \mu^{-1}(\mathcal{E})\widehat{\otimes}_{\mu^{-1}(\mathcal{O}_D)}\mathcal{O}_{\mathfrak{X}} \to \mathfrak{X}$  denote the pull-back sheaf. It is a coherent analytic sheaf of  $\mathcal{O}_{\mathfrak{X}}$ -modules. Now  $[\sigma] \mapsto [\sigma] \otimes 1$  defines a map  $i : \mu^{-1}(\mathcal{E}) \to \mu^*(\mathcal{E})$  which in turn specifies maps in cohomology, the coefficient morphisms

$$i_p: H^p(\mathfrak{X}; \mu^{-1}(\mathcal{E})) \to H^p(\mathfrak{X}; \mu^*(\mathcal{E})) \quad \text{for } p \ge 0.$$
 (2.6)

Our natural pull-back maps are the compositions  $j^{(p)} = i_p \cdot \mu^{(p)}$  of (2.3) and (2.6):

$$j^{(p)}: H^p(D; \mathcal{E}) \to H^p(\mathfrak{X}; \mu^*(\mathcal{E})) \quad \text{for } p \ge 0.$$
(2.7)

We have  $\mathcal{E} = \mathcal{O}(\mathbb{E})$  for some holomorphic vector bundle  $\mathbb{E} \to D$ , because we assumed  $\mathcal{E} \to D$  locally free. Thus  $\mu^*(\mathcal{E}) = \mathcal{O}(\mu^*(\mathbb{E}))$  and we realize these sheaf cohomologies as Dolbeault cohomologies. In the context of Dolbeault cohomology, the pull-back maps (2.7) are given by pulling back  $[\omega] \mapsto [\mu^*(\omega)]$  on the level of differential forms.

#### Push-down.

In order to push the  $H^q(\mathfrak{X};\mu^*(\mathcal{E}))$  down to  $\mathcal{M}$  we assume that

$$\mathcal{M}$$
 is a Stein manifold. (2.8)

Since  $\nu : \mathfrak{X} \to \mathcal{M}$  was assumed proper, we have the Leray direct image sheaves  $\mathcal{R}^p(\mu^*(\mathcal{E})) \to \mathcal{M}$ . Those sheaves are coherent [13]. As  $\mathcal{M}$  is Stein

$$H^q(\mathcal{M}; \mathcal{R}^p(\mathcal{E})) = 0 \quad \text{for} \quad p \ge 0 \text{ and } q > 0.$$
 (2.9)

Thus the Leray spectral sequence of  $\nu : \mathfrak{X} \to \mathcal{M}$  collapses and gives

$$H^{p}(\mathfrak{X};\mu^{*}(\mathcal{E})) \cong H^{0}(\mathcal{M};\mathcal{R}^{p}(\mu^{*}(\mathcal{E}))).$$
(2.10)

**Definition.** The *double fibration transform* for the double fibration (2.1) is the composition

$$\mathcal{P}: H^p(D; \mathcal{E}) \to H^0(\mathcal{M}; \mathcal{R}^p(\mu^*(\mathcal{E})))$$
(2.11)

of the maps (2.7) and (2.10).

In order that the double fibration transform (2.11) be useful, one wants two conditions to be satisfied. They are

$$\mathcal{P}: H^p(D; \mathcal{E}) \to H^0(\mathcal{M}; \mathcal{R}^p(\mu^*(\mathcal{E}))) \text{ should be injective, and}$$
 (2.12)

there should be an explicit description of the image of  $\mathcal{P}$ . (2.13)

Assuming (2.8), injectivity of  $\mathcal{P}$  is equivalent to injectivity of  $j^{(p)}$  in (2.7). The most general way to approach this is the combination of vanishing and negativity in Theorem 2.14 below, taking the Buchdahl conditions (2.4) into consideration.

Given the setting of (2.8) our attack on the injectivity question uses a spectral sequence argument for the relative de Rham complex of the holomorphic submersion  $\mu: \mathfrak{X} \to D$ . See [23] for the details. The end result is

**Theorem 2.14.** Let  $\mathcal{E} = \mathcal{O}(\mathbb{E})$  for some holomorphic vector bundle  $\mathbb{E} \to D$ . Fix  $q \geq 0$ . Suppose that the fiber F of  $\mu : \mathfrak{X} \to D$  is connected and satisfies (2.4). Assume (2.8) that  $\mathcal{M}$  is Stein. Suppose that  $H^p(C; \Omega^r_{\mu}(\mathbb{E})|_C) = 0$  for p < q, and  $r \geq 1$  for every fiber C of  $\nu : \mathfrak{X} \to \mathcal{M}$  where  $\Omega^r_{\mu}(\mathbb{E}) \to \mathfrak{X}$  denotes the sheaf of relative  $\mu^*\mathbb{E}$ -valued holomorphic r-forms on  $\mathfrak{X}$  with respect to  $\mu : \mathfrak{X} \to D$ . Then  $\mathcal{P}: H^q(D; \mathcal{E}) \to H^0(\mathcal{M}; \mathcal{R}^q(\mu^*\mathcal{E}))$  is injective.

#### Flag domain case.

In the cases of interest to us, D will be a flag domain, we will have  $\mathcal{E} = \mathcal{O}(\mathbb{E})$  as in Theorem 2.14, and the transform  $\mathcal{P}$  will have an explicit formula. The Leray derived sheaf will be given by

$$\mathcal{R}^{q}(\mu^{*}(\mathcal{O}(\mathbb{E}))) = \mathcal{O}(\mathbb{E}') \text{ where}$$
  
$$\mathbb{E}' \to \mathcal{M} \text{ has fiber } H^{q}(\nu^{-1}(C); \mathcal{O}(\mu^{*}(\mathbb{E})|_{\nu^{-1}(C)})) \text{ at } C.$$
(2.15)

Then  $\mathcal{P}$  will be given on the level of Dolbeault cohomology, as follows. Let  $\omega$  be an  $\mathbb{E}$ -valued (0,q)-form on D and  $[\omega] \in H^{q}_{\overline{\partial}}(D,\mathbb{E})$  its Dolbeault class. Then

$$\mathcal{P}([\omega])$$
 is the holomorphic section of  $\mathbb{E}' \to \mathcal{M}$   
whose value  $\mathcal{P}([\omega])(C)$  at  $C \in \mathcal{M}$  is  $[\mu^*(\omega)|_{\nu^{-1}(C)}]$ 

In other words,

$$\mathcal{P}([\omega])(C) = [\mu^*(\omega)|_{\nu^{-1}(C)}] \in H^0_{\overline{\partial}}(\mathcal{M}; \mathbb{E}')$$
(2.16)

This is most conveniently interpreted by viewing  $\mathcal{P}([\omega])(C)$  as the Dolbeault class of  $\omega|_C$ , and by viewing  $C \mapsto [\omega|_C]$  as a holomorphic section of the holomorphic vector bundle  $\mathbb{E}' \to \mathcal{M}$ . Now let  $D = G_0(z_0)$  be an open orbit in the complex flag manifold Z = G/Q, and  $\mathcal{M}$  is replaced by the cycle space  $\mathcal{M}_D$ . Our double fibration (2.1) is replaced by

$$\begin{array}{c}
\mu \swarrow & \mathfrak{X}_D \\
D & \mathcal{M}_D \\
\end{array} (2.17)$$

where  $\mathfrak{X}_D := \{(z, C) \in D \times \mathcal{M}_D \mid z \in C\}$  is the incidence space. Given a  $G_0$ -homogeneous holomorphic vector bundle  $\mathbb{E} \to D$ , and the number  $q = \dim_{\mathbb{C}} C_0$ , we will see in Section 4. that the Leray derived sheaf involved in the double fibration transform satisfies (2.15). Here (2.15) will become a little bit more explicit and take the form

$$\mathcal{R}^{q}(\mu^{*}(\mathcal{O}(\mathbb{E}))) = \mathcal{O}(\mathbb{E}') \text{ where}$$
$$\mathbb{E}' \to \mathcal{M}_{D} \text{ has fiber } H^{q}(C; \mathcal{O}(\mathbb{E}|_{C})) \text{ at } C \in \mathcal{M}_{D} .$$
(2.18)

Evidently,  $\mathbb{E}' \to \mathcal{M}_D$  will be globally  $G_0$ -homogeneous. It cannot be G-homogeneous unless  $\mathcal{M}_D$  is G-invariant, and that only happens in the degenerate case where  $G_0$  is transitive on Z. However, in Section 4. we will see that  $\mathbb{E}' \to \mathcal{M}_D$  is the restriction of a G-homogenous holomorphic vector bundle  $\widetilde{\mathbb{E}}' \to \mathcal{M}_Z$ , and in particular (2.15) is satisfied. In any case,  $H^q(C; \mathcal{O}(\mathbb{E}|_C))$  can be calculated from the Bott–Borel–Weil Theorem. Thus  $\mathcal{R}^q(\mu^*(\mathcal{O}(\mathbb{E})))$  will be given explicitly by (2.18) in the flag domain case.

Using methods of complex geometry as described in Section 3. below it was shown ([17] plus [10]) that  $\mathcal{M}_D$  is biholomorphically equivalent to a certain universal domain  $\mathcal{U}$  or to a bounded symmetric domain. It follows in general that  $\mathcal{M}_D$  is a contractible Stein manifold, so  $\mathbb{E}' \to \mathcal{M}_D$  is holomorphically trivial. We will use those same methods in Section 5. to construct certain holomorphic fibrations of the  $\mathcal{M}_D$  and use those "Schubert fibrations" to show that F satisfies (2.4) for all q. That is how we will prove that the double fibration transforms are injective. Thus, in the flag domain case, we will have a complete answer to (2.12) and some progress toward (2.13).

#### 3. A Computable Description of $\mathcal{M}_D$

In order to understand the structure of Z, D and  $\mathcal{M}_D$  we may assume that  $G_0$  is simple, because  $G_0$  is local direct product of simple groups, and Z, D and  $\mathcal{M}_D$ break up as global direct products along the local direct product decomposition of  $G_0$ . From this point on  $G_0$  is simple unless we say otherwise. We also assume that  $G_0$  is not compact, and we avoid the two trivial noncompact cases (see [22]), where  $G_0$  acts transitively on Z so that  $\mathcal{M}_D$  is reduced to a single point.

As above let  $\mathcal{M}_Z := G.C_0$ . Since  $C_0$  is a complex manifold, the isotropy group  $G_{C_0}$  contains the complexification K of  $K_0$ , which is a closed complex subgroup of G. If  $G_0$  is not Hermitian, then  $\mathfrak{k}$  is a maximal subalgebra of  $\mathfrak{g}$ , so  $G_{C_0}/K$  is finite. In this nonhermitian case, without further discussion, we replace  $\mathcal{M}_Z$  by the finite cover G/K. There is no loss of generality in doing this because, as we will see later,  $\mathcal{M}_D$  pulls back biholomorphically to a domain in G/K under the finite covering  $G/K \to G.C_0$ . If  $G_0$  is Hermitian, then the symmetric space  $G_0/K_0$  possesses two invariant complex structures,  $\mathcal{B}$  and  $\overline{\mathcal{B}}$ , as bounded Hermitian symmetric domains. These are realized as open orbits D in their compact duals G/P and  $G/\bar{P}$  respectively. In these cases the base cycles are just the  $K_0$  fixed points and clearly  $G_{C_0}$  is either P or  $\overline{P}$  in such a situation; in particular, as opposed to being the affine homogeneous space G/K, the space  $\mathcal{M}_Z$  is a compact homogeneous manifold.

The above mentioned phenomenon is characterized by  $G_{C_0}$  being either P or  $\overline{P}$ . It occurs in more interesting situations than just that where D itself is a bounded domain, but it should be regarded as an exceptional case which is completely understood [21]. In particular, in any such example the cycle space  $\mathcal{M}_D$  is either  $\mathcal{B}$  or  $\overline{\mathcal{B}}$ .

In all other cases it was recently shown that  $\mathcal{M}_D$  is naturally biholomorphic to a universal domain  $\mathcal{U} \subset \mathcal{M}_Z = G/K$  ([10], [17]). It should be emphasized that  $\mathcal{U}$ , which we now define, depends *only* on the real form  $G_0$ , and not on D.

The domain  $\mathcal{U}$  can be defined in a number of different ways. We choose the historical starting point which is of a differential geometric nature.

Let M denote the Riemannian symmetric space  $G_0/K_0$  of negative curvature and consider its tangent bundle TM. As usual let  $\theta$  be a Cartan involution of  $\mathfrak{g}$  that commutes with complex conjugation over its real form  $\mathfrak{g}_0$ .  $\theta$  defines the Cartan decompositions  $\mathfrak{g} = \mathfrak{g}_u \oplus i\mathfrak{g}_u$  and  $\mathfrak{g}_0 = \mathfrak{k}_0 \oplus \mathfrak{s}_0$ , where  $\mathfrak{g}_u$  is the compact real form of  $\mathfrak{g}$  with  $\mathfrak{k}_0 = \mathfrak{g}_u \cap \mathfrak{g}_0$ .

We identify  $\mathfrak{s}_0$  with  $TM_{x_0}$ , where  $x_0$  is the base point with  $G_0$ -isotropy  $K_0$ , and regard TM as the homogeneous bundle  $G_0 \times_{K_0} \mathfrak{s}_0$ . One defines the *polar* coordinates mapping by

$$\Pi: TM \to G/K, \ ([g_0,\xi]) \mapsto g_0 \exp(i\xi).x_0.$$

Clearly  $\Pi$  is a diffeomorphism in a neighborhood of the 0–section and thus it is of interest to consider the canonically defined domain

$$\Omega_{max} := \{ v \in TM : \operatorname{rank}(\Pi_*(v)) = \dim TM \}^0.$$

Here the connected component is that which contains the 0-section.

It turns out that  $\Omega_{max}$  is determined by differential geometric properties of the compact dual  $N := G_u \cdot x_0 = G_u / K_0$ , where  $G_u$  is the maximal compact subgroup of G defined by  $\mathfrak{g}_u$ . For this it is essential that the geodesics emanating from  $x_0$  in N are just orbits  $\exp(i\xi) \cdot x_0$ ,  $\xi \in \mathfrak{s}_0$ , of 1-parameter groups.

Let  $\frac{1}{2}N$  denote the set of points in N which are at most halfway from  $x_0$  to the cut point locus and define  $\Omega_C = G_0 \cdot \frac{1}{2}N$ .

**Theorem 3.1.** (Crittenden [8]) The polar coordinates mapping  $\Pi$  restricts to a diffeomorphism from  $\Omega_{max}$  to  $\Omega_C$ .

The domain  $\Omega_C$  can be computed in an elementary way. For this regard  $K_0$  as acting on  $\mathfrak{s}_0$  by the adjoint representation, let  $\mathfrak{a}_0$  be a maximal Abelian subalgebra in  $\mathfrak{s}_0$  and recall that  $K_0.\mathfrak{a}_0 = \mathfrak{s}_0$ . Thus  $\Omega_C$  is determined by a domain in  $\mathfrak{a}_0$ . This is computed as follows.

Since  $\mathfrak{a}_0$  acts on  $\mathfrak{g}_0$  as a commutative algebra of self-adjoint transformations, the associated joint eigenvalues  $\alpha \in \mathfrak{a}_0^*$  are real valued. (The nonzero ones are the  $(\mathfrak{g}_0, \mathfrak{a}_0)$ -roots or *restricted* roots.) Consider the convex polygon

 $V = \{\xi \in \mathfrak{a}_0 \mid |\alpha(\xi)| < \frac{\pi}{2} \text{ for all restricted roots } \alpha\}$ 

and define

 $\mathcal{U} := G_0 \cdot \exp(iV) \cdot x_0.$ 

**Theorem 3.2.** ([8], [1])  $\Omega_C = \mathcal{U}$ .

**Remark 3.3.** The domain  $\mathcal{U}$ , which is indeed explicitly computable, was first brought to our attention by the work in [1]. As a consequence we originally denoted it by  $\Omega_{AG}$ . It turns out that it is naturally equivalent to a number of other domains, including the cycle spaces, which are defined from a variety of viewpoints. So now, unless we have a particular construction in mind, we denote it by  $\mathcal{U}$  to underline its universal character.

**Proposition 3.4.** The domain  $\mathcal{U}$  is contractible.

**Proof.** For this we regard  $\mathcal{U}$  as being contained in TM. Since V is a (polyhedral) domain in  $\mathfrak{s}_0$  star-shaped from 0, scalar multiplication  $\varphi_t : TM \times TM$ ,  $v \mapsto tv$ , stabilizes V, and for  $0 \leq t \leq 1$  defines a strong deformation retraction of  $\mathcal{U}$  to the 0-section M. That 0-section is also contractible.

Complex geometric properties of  $\mathcal{U}$  are also of importance. These include the fact that  $\mathcal{U}$  is a Stein domain in  $\mathcal{M}_{\mathcal{Z}}$  ([7]; also see [3], [16], [17], [11], [12]).

For later reference let us state the main points in the context of cycle spaces.

**Theorem 3.5.** If D is not one of the above exceptions where  $\mathcal{M}_D$  is either a single point or  $\mathcal{B}$  or  $\overline{\mathcal{B}}$ , then  $\mathcal{M}_D = \mathcal{U}$ . Thus in all cases  $\mathcal{M}_D$  is contractible and Stein.

**Corollary 3.6.** Let  $P \subset Q$  be parabolic subgroups of G. Let  $\pi$  denote the natural projection  $1P \mapsto 1Q$  of W = G/P onto Z = G/Q. Suppose that the flag domain  $D \subset Z$  is not one of the above exceptions where  $\mathcal{M}_D$  is either a single point or  $\mathcal{B}$  or  $\overline{\mathcal{B}}$ . Let  $\widetilde{D} \subset W$  be a flag domain such that  $\pi(\widetilde{D}) = D$ . Then  $\pi$  induces a holomorphic diffeomorphism of  $\mathcal{M}_{\widetilde{D}}$  onto  $\mathcal{M}_D$ .

# 4. Globalization of the Bundles

We will show that various bundles are restrictions of bundles homogeneous under the complex group G, and use that to carry bundles over D to bundles over  $\mathcal{M}_D$ . For that we need an old result on homogeneous holomorphic vector bundles from [19, Section 3].

 $M = A_0/B_0$  be a homogeneous complex manifold. Let  $p: A_0 \to M$  denote the natural projection. View the Lie algebra  $\mathfrak{a}_0$ , and thus its complexification  $\mathfrak{a}$ , as Lie algebras of holomorphic vector fields on M. Let  $m \in M$  denote the base point  $1B_0$  and define  $\mathfrak{p} = \{\xi \in \mathfrak{a} \mid \xi_m = 0\}$ . Then  $\mathfrak{p}$  is an  $\mathrm{Ad}(B_0)$ -stable complex subalgebra of  $\mathfrak{a}$  such that  $\mathfrak{a} = \mathfrak{p} + \overline{\mathfrak{p}}$  and  $\mathfrak{b} = \mathfrak{p} \cap \overline{\mathfrak{p}}$ . Here  $\mathfrak{b}$  is the complexification of the Lie algebra  $\mathfrak{b}_0$  of  $B_0$ . Let  $\chi$  be a continuous representation of  $B_0$  on a finite dimensional complex vector space  $E = E_{\chi}$ . By *extension of*  $\chi$  to  $\mathfrak{p}$  we mean a Lie algebra representation  $\lambda$  of  $\mathfrak{p}$  on E such that  $\lambda|_{\mathfrak{b}_0} = d\chi$  and  $\lambda(\operatorname{Ad}(b)\xi) = \chi(b)\lambda(\xi)\chi(b)^{-1}$  for all  $b \in B_0$ and  $\xi \in \mathfrak{p}$ . Thus an extension of  $\chi$  to  $\mathfrak{p}$  is a  $(\mathfrak{p}, B_0)$ -module structure on  $E_{\chi}$ .

The representation  $\chi$  defines a real analytic,  $A_0$ -homogeneous, complex vector bundle  $\mathbb{E}_{\chi} \to M = A_0/B_0$ , by  $\mathbb{E}_{\chi} = A_0 \times_{B_0} E_{\chi}$ . We identify local sections  $s: U \to \mathbb{E}_{\chi}$  with functions  $f_s: p^{-1}(U) \to E_{\chi}$  such that  $f_s(gb) = \chi(b)^{-1} f_s(b)$ .

The holomorphic vector bundle structures on  $\mathbb{E}_{\chi} \to M$  are given as follows.

**Theorem 4.1.** [19, Theorem 3.6] The structures of  $A_0$ -homogeneous holomorphic vector bundle on  $\mathbb{E}_{\chi} \to M$  are on one to one correspondence with the extensions  $\lambda$  of  $\chi$  from  $B_0$  to  $\mathfrak{p}$ . The structure corresponding to  $\lambda$  is the one for which the holomorphic sections s over any open set  $U \subset M$  are characterized by  $\xi \cdot f_s + \lambda(\xi)f_s = 0$  on  $p^{-1}(U)$  for all  $\xi \in \mathfrak{p}$ .

Now we return to the flag domain setting and extend the double fibration (2.17) to

where  $\mathcal{M}_Z = \{gC_0 \mid g \in G\}$  and  $\mathfrak{X}_Z := \{(z, C) \in Z \times \mathcal{M}_Z \mid z \in C\}$  is the incidence space. Evidently  $\mathcal{M}_D$  is an open submanifold of  $\mathcal{M}_Z$ , and  $\mu$  and  $\nu$  are the respective restrictions of  $\tilde{\mu}$  and  $\tilde{\nu}$ .

**Theorem 4.3.** Let D be an open  $G_0$ -orbit on Z, let  $\mathbb{E} \to D$  be a  $G_0$ homogeneous holomorphic vector bundle, and let  $q \geq 0$ . Suppose  $G_0 \subset G$ . Then (1)  $\mathbb{E} \to D$  is the restriction of a G-homogeneous holomorphic vector bundle  $\widetilde{\mathbb{E}} \to Z$ , (2) the Leray derived sheaf for  $\widetilde{\nu}$  is given by  $\mathcal{R}^q(\mathcal{O}(\widetilde{\mu}^*\widetilde{\mathbb{E}})) = \mathcal{O}(\widetilde{\mathbb{E}}')$ where  $\widetilde{\mathbb{E}}' \to \mathcal{M}_Z$  is the G-homogeneous, holomorphic vector bundle with fiber  $H^q(C; \mathcal{O}(\widetilde{\mathbb{E}}|_C))$  over  $C \in \mathcal{M}_Z$ , and (3) the Leray derived sheaf for  $\nu$  is given by  $\mathcal{R}^q(\mathcal{O}(\mu^*\mathbb{E})) = \mathcal{O}(\mathbb{E}')$  where  $\mathbb{E}'$  is the restriction of  $\widetilde{\mathbb{E}}'$  to  $\mathcal{M}_D$ .

**Proof.** We translate the result of Theorem 4.1 to our situation of the flag domain  $D = G_0(z) \cong G_0/L_0$  where  $L_0 = G_0 \cap Q_z$  is the isotropy subgroup of  $G_0$  at z. Here  $G_0$  replaces  $A_0$ ,  $L_0$  replaces  $B_0$ ,  $E = E_{\chi}$  is the fiber of  $\mathbb{E} \to D$ over z, the representation  $\chi$  is the action of  $L_0$  on E, and  $\mathfrak{q}_z$  replaces  $\mathfrak{p}$ . The homogeneous holomorphic vector bundle structure on  $\mathbb{E} \to D$  comes from an extension  $\lambda$  of  $\chi$  from  $L_0$  to  $\mathfrak{q}_z$ . Here  $\lambda$  integrates to  $L_0$  by construction and then to  $Q_z$  because  $G_0 \subset G$ . Thus we have a holomorphic representation  $\tilde{\chi}$  of  $Q_z$  on E that extends  $\chi$ . That defines the G-homogeneous holomorphic vector bundle  $\widetilde{\mathbb{E}} \to G/Q_z = Z$ , and  $\mathbb{E} = \widetilde{\mathbb{E}}|_D$  by construction. Statement (1) is proved.

By *G*-homogeneity of  $\widetilde{\mathbb{E}} \to Z$  all the  $\widetilde{\mathbb{E}}|_C \to C$  are holomorphically equivalent. Now (2) follows from the construction of Leray derived sheaves. The same considerations prove (3).

## 5. The Method of Schubert Slices

Schubert slices play a major role in the classification part of the above theorem (see [10] and [17]). Here we present the mini-version of this theory which is all that is needed for our applications in §6. (see [16]).

Let us begin by recalling that a Borel subgroup B of G has only finitely many orbits in Z. Such an orbit  $\mathcal{O}$  is called a Schubert cell,  $\mathcal{O} \cong \mathbb{C}^{m(\mathcal{O})}$ , and its closure  $S = \overline{\mathcal{O}} = \mathcal{O} \cup Y$  is referred to as the associated Schubert variety. The set  $S = \{S\}$  of all B-Schubert varieties freely generates the integral homology  $H_*(Z)$ .

If  $G_0 = K_0 A_0 N_0$  is an Iwasawa decomposition and  $B \supset A_0 N_0$ , then we refer to B as an Iwasawa–Borel subgroup. Recalling that a given Borel subgroup has a unique fixed point in Z = G/Q, it follows that the Iwasawa–Borel groups are exactly those which fix a point of the closed  $G_0$ –orbit in Z.

We now prove several elementary propositions.

**Proposition 5.1.** Let D be an open  $G_0$ -orbit in Z,  $C_0$  the base cycle in Dand  $z \in D$ . Then  $A_0N_0.z \cap C_0 \neq \emptyset$ . In particular, if B is an Iwasawa-Borel subgroup, then every B-orbit  $\mathcal{O}$  which has non-empty intersection with D satisfies  $\mathcal{O} \cap C_0 \neq \emptyset$ .

**Proof.** Since  $G_0 = A_0 N_0 K_0$  and  $C_0$  is a  $K_0$ -orbit in D, it is immediate that  $D = A_0 N_0 C_0$ .

The following holds for similar reasons.

**Lemma 5.2.** If  $z \in D$  then  $T_z(K_0.z) + T_z(A_0N_0.z) = T_zD$ .

**Proposition 5.3.** If S is a Schubert variety of an Iwasawa–Borel subgroup B with  $\operatorname{codim}_{\mathbb{C}}S > q$ , then  $S \cap D = \emptyset$ .

**Proof.** Let  $\mathcal{O}$  be the open dense B-orbit in S. If  $S \cap D \neq \emptyset$ , then  $\mathcal{O} \cap D \neq \emptyset$  as well. Thus, by Proposition 5.1,  $\mathcal{O} \cap C_0 \neq \emptyset$ . But if  $z \in \mathcal{O} \cap C_0$  then  $\dim_{\mathbb{R}} A_0 N. z < \operatorname{codim}_{\mathbb{R}} K_0. z$  would contradict Lemma 5.2.

We now come to a basic fact.

**Proposition 5.4.** If  $\operatorname{codim}_{\mathbb{C}}S = q$  and  $S \cap D \neq \emptyset$ , then  $S \cap C_0 = \{z_1, \ldots, z_d\}$  is non-empty, finite and contained in the *B*-orbit  $\mathcal{O}$ . This intersection is transversal in the sense that

 $T_{z_i}C_0 \oplus T_{z_i}\mathcal{O} = T_{z_i}Z$ 

for all *i*. Furthermore,  $\Sigma_i := A_0 N_0 z_i$  is open in  $\mathcal{O}$  and closed in D.

**Proof.** Proposition 5.1 tells us that  $S \cap C_0$  is non-empty. If  $S \cap C_0$  is infinite, then it has positive dimension at one or more of its points, contrary to Lemma 5.2. The same argument proves the transversality and the fact that  $A_0N_0.z_i$  is open in  $\mathcal{O}$ . If  $\Sigma_i$  were not closed in  $\mathcal{O}$ , then we would find an  $A_0N_0$ -orbit of smaller dimension on its boundary. By Proposition 5.1 this  $A_0N_0$ -orbit would meet  $C_0$ , contrary to Lemma 5.2.

An  $A_0N_0$ -orbit  $\Sigma$  as above is called a *Schubert slice*. Since  $[C_0]$  is non-zero in  $H_*(Z;\mathbb{Z})$  and  $S = \{S\}$  generates this homology, every Iwasawa-Borel subgroup B gives us q-codimensional Schubert varieties with non-empty intersection  $S \cap D$ . In particular, there exist such Schubert slices.

It is known that D is retractable to  $C_0$  ([20], see also [17]) and therefore  $\pi_1(D) = 1$ . Let us translate this into a statement on the isotropy groups along the base cycle.

**Lemma 5.5.** If  $\Sigma$  is a Schubert slice and  $z \in \Sigma \cap C_0$ , then

$$\alpha: (K_0)_z \times (A_0 N_0)_z \to (G_0)_z, \ (k_0, a_0 n_0) \mapsto k_0 a_0 n_0,$$

is bijective.

**Proof.** Since  $K_0$  is compact and  $A_0N_0$  is closed in  $G_0$ , it follows that  $\alpha$  is a diffeomorphism onto a closed submanifold of  $G_0$ . A dimension count shows that it is open in  $G_z$ . But  $G_z$  is connected, because  $\pi_1(D) = 1$ . Thus the image of  $\alpha$  is all of  $G_z$ .

We now come to the main result of this section.

**Theorem 5.6.** If  $\Sigma$  is a Schubert slice, then for every  $C \in \mathcal{M}_D$  the intersection  $\Sigma \cap C$  is transversal and consists of exactly one point.

**Proof.** First, we prove this for  $C = C_0$ . Let  $z_0 \in C_0 \cap \Sigma$ . If  $z_1 = a_0 n_0 . z_0$  were any other point in this intersection, then  $z_1 = k_0^{-1} . z_0$  for some  $k_0 \in K_0$ . But then  $g_0 = k_0 a_0 n_0 \in (G_0)_{z_0}$  and consequently by Lemma 5.5 both  $k_0$  and  $a_0 n_0$  fix  $z_0$ , i.e.,  $z_1 = z_0$  is the unique point in  $C_0 \cap \Sigma$ .

Now let  $C \in \mathcal{M}_D$  be an arbitrary element of the cycle space. Denote by  $\mathcal{O}$  the open *B*-orbit in the Schubert variety  $S = \mathcal{O} \dot{\cup} Y$  which contains  $\Sigma$ . Since  $\mathcal{O} \cong \mathbb{C}^{m(\mathcal{O})}$  is Stein, if  $C \cap \Sigma$  were positive-dimensional then  $C \cap Y \neq \emptyset$ . But  $\operatorname{codim}_{\mathbb{C}} Y > q$  and therefore  $Y \cap D = \emptyset$ . Thus this would be contrary to  $C \subset D$ . Now  $C \cap D$  is finite.

If  $C \cap \Sigma$  is empty we obtain a contradiction as follows. Let  $C_t$  be a curve from  $C_0$  to C in  $\mathcal{M}_D$ . Define

$$t_0 := \sup\{t : C_s \cap \Sigma \neq \emptyset \text{ for all } s < t\}.$$

Then there is a sequence  $\{z_n\} \subset D$  with  $z_n \in C_{t_n}$  corresponding to  $\{t_n\}$  such that  $\{t_n\} \to t_0$  and  $\{z_n\} \to z_0 \in bd(\Sigma) \subset bd(D)$ . Therefore  $C_{t_0} \cap bd(D) \neq \emptyset$ , contrary to  $C_{t_0} \in \mathcal{M}_D$ .

This argument holds for each of the  $\Sigma_i$ . In particular,  $C \cap S$  contains at least d distinct (isolated) points. Since  $[C] \cdot [S] = d$ , it follows that  $|C \cap S| = d$  and that the intersection at each of these points is transversal.

## 6. Canonical Fibrations and DFT–Injectivity

Let  $\Sigma$  be a Schubert slice defined by an Iwasawa–Borel subgroup B, denote  $\{z_0\} = \Sigma \cap C_0$ , In the context of the double fibration (2.17), the projection  $\nu$ 

carries the fiber  $F = \mu^{-1}(z_0) = \{(z_0, C) : z_0 \in C\}$  biholomorphically onto the analytic subset  $\{C \in \mathcal{M}_D : z_0 \in C\}$  of  $\mathcal{M}_D$ .

Now consider an arbitrary element  $C \in \mathcal{M}_Z$  with  $z_0 \in C$ . By definition  $C = g(C_0)$  for some  $g \in G$ . Since  $z_0 \in C$ , by adjusting g by an appropriate element of  $K_0$  we may assume that  $g \in Q = G_{z_0}$ . Thus  $\widetilde{F} \cong \{C \in \mathcal{M}_Z : z_0 \in C\} = Q.C_0$ .  $\widetilde{F}$  is closed in  $\mathcal{M}_Z$ , for if a net  $\{C_i\}$  in  $\widetilde{F}$  converges to  $C \in \mathcal{M}_Z$  then  $z_0 \in C$  because  $z_0 \in C_i$  for each i, so  $C \in \widetilde{F}$ .

The Z-analog of the double fibration (2.17) is given by (4.2). There the Q-orbit  $\widetilde{F} \subset \mathcal{M}_Z$  is identified with the fiber  $\widetilde{\mu}^{-1}(z_0)$ . In particular, its open subset  $F = \widetilde{F} \cap \mathcal{M}_D$  is a closed complex submanifold on  $\mathcal{M}_D$ .

By Theorem 5.6, an  $A_0N_0$ -equivariant map  $\varphi : \mathcal{M}_D \to \Sigma$  is defined by mapping C to its point of intersection with  $\Sigma$ . The fiber over  $z_0 \in \Sigma$  is of course F.

Let  $J_0 := (A_0 N_0)_{z_0}$  be the  $A_0 N_0$ -isotropy at the base point and note that

 $A_0 N_0 \times_{J_0} F \to \mathcal{M}_D$ , defined by  $[(a_0 n_0, C)] \mapsto a_0 n_0(C)$ ,

is well-defined, smooth and bijective. Thus  $\varphi : \mathcal{M}_D \to \Sigma$  is naturally identified with the smooth  $A_0 N_0$ -equivariant bundle

$$\pi_{\Sigma}: A_0 N_0 \times_{J_0} F \to A_0 N_0 / J_0 = \Sigma.$$

In this sense, every Schubert slice defines a *Schubert fibration* of the cycle space  $\mathcal{M}_D$ .

**Theorem 6.1.** Let B be an Iwasawa–Borel subgroup of G and  $\Sigma$  an associated Schubert slice for the open orbit D. Then the fibration  $\pi_{\Sigma} : \mathcal{M}_D \to \Sigma$  is a holomorphic map on to a contractible base  $\Sigma$  and diffeomorphically realizes  $\mathcal{M}_D$ as the product  $\Sigma \times F$ .

**Proof.** Let  $J := B_{z_0}$ . The inclusions  $A_0 N_0 \hookrightarrow B$  and  $F \hookrightarrow \widetilde{F}$  together define a map  $A_0 N_0 \times_{J_0} F \hookrightarrow B \times_J F$ . That map realizes  $A_0 N_0 \times_{J_0} F \cong \mathcal{M}_D$  as an open subset of  $B \times_J \widetilde{F}$ . The latter is fibered over the open  $A_0 N_0$ -orbit  $\Sigma$  in  $\mathcal{O} = B.z_0$  by the natural holomorphic projection  $\pi : B \times_J \widetilde{F} \to B/J$ . Since  $\pi_{\Sigma}$  is the restriction  $\pi|_{\mathcal{M}_D}$ , it follows that  $\pi_{\Sigma}$  is holomorphic as well.

The fact that  $\Sigma$  is a cell follows form the simple connectivity of the solvable group  $A_0N_0$  and the fact that it is acting algebraically.

Recall the notation:  $\Omega^r_{\mu}(\mathbb{E}) \to \mathfrak{X}_D$  is the sheaf of relative  $\mu^*\mathbb{E}$ -valued holomorphic *r*-forms on  $\mathfrak{X}$  with respect to  $\mu : \mathfrak{X}_D \to D$ .

**Corollary 6.2.** Suppose that  $\mathbb{E} \to D$  a holomorphic  $G_0$ -homogeneous vector bundle which is sufficiently negative so that  $H^p(C; \Omega^r_\mu(\mathbb{E})|_C) = 0$  for p < q, and  $r \geq 1$ . Then the double fibration transform

$$\mathcal{P}: H^q(D, \mathcal{O}(\mathbb{E})) \to H^0(M, \mathcal{O}(\mathbb{E}'))$$

is injective.

**Proof.**  $\mathcal{M}_D$  is contractible by Proposition 3.4. Since  $\Sigma$  is likewise contractible and  $\mathcal{M}_D$  is diffeomorphic to  $\Sigma \times F$ , it follows that F is cohomologically trivial. The Buchdahl conditions (2.4) follow. Proposition 2.5 now says that (2.3) is an isomorphism for all r. Composing with coefficient morphisms, the maps (2.6) also are isomorphisms. By Theorem 3.5 we know that the conditions (2.8) are satisfied. The assertion now follows from Theorem 2.14.

With a bit more work one can see that the fiber F of  $\mathcal{M}_D \to \Sigma$  is contractible, not just cohomologically trivial. We thank Peter Michor for showing us the following result for the  $C^{\infty}$  category, from which contractibility of F is immediate. His argument is based on the existence of a complete Ehresmann connections for smooth fiber bundles.

**Proposition 6.3.** Let  $p: M \to S$  be a smooth fiber bundle with fiber  $F = p^{-1}(s_0)$ . If both M and S are contractible then F is contractible.

**Proof.** Since S is contractible and smooth, approximation gives us a smooth contraction  $h : [0,1] \times S \to S$ ; here h(0,s) = s and  $h(1,s) = s_0$ . Following [18, §9.9] the bundle  $p : M \to S$  has a complete Ehresmann connection. Completeness means that every smooth curve in S has horizontal lifts to M. If  $m \in M$  let  $t \mapsto H(t,m)$  denote the horizontal lift of  $t \mapsto h(t,p(m))$  such that H(0,m) = m. Note  $H(1,m) \in F$ . Fix a base point  $m_0 \in M$  and a smooth contraction  $I : [0,1] \times M \to M$  of M to  $m_0$ ; if  $m \in M$  then I(0,m) = m and  $I(1,m) = m_0$ . Denote  $f_0 = H(1,m_0) \in F$ . Define  $J : [0,1] \times F$  by J(t,f) = H(t,I(t,f)), so J(0,f) = f and  $J(1,f) = f_0$ . Thus J is a contraction of F to  $f_0$ , and so F is contractible.
