Divisibility in rings of integer-valued polynomials

Felix Gotti and Bangzheng Li

Abstract. In this paper, we address various aspects of divisibility by irreducibles in rings consisting of integer-valued polynomials. An integral domain is called atomic if every nonzero nonunit factors into irreducibles. Atomic domains that do not satisfy the ascending chain condition on principal ideals (ACCP) have proved to be elusive, and not many of them have been found since the first one was constructed by A. Grams in 1974. Here we exhibit the first class of atomic rings of integer-valued polynomials without the ACCP. An integral domain is called a finite factorization domain (FFD) if it is simultaneously atomic and an idf-domain (i.e., every nonzero element is divisible by only finitely many irreducibles up to associates). We prove that a ring is an FFD if and only if its ring of integer-valued polynomials is an FFD. In addition, we show that being an idf-domain does not transfer, in general, from an integral domain to its ring of integer-valued polynomials. In the same class of rings of integer-valued polynomials, we consider further properties that are defined in terms of divisibility by irreducibles, including being Cohen-Kaplansky and being Furstenberg.

1. Introduction

Let \( R \) be an integral domain with quotient field \( K \), and let \( S \) be a subset of \( R \). The ring of integer-valued polynomials of \( R \) on \( S \), denoted by \( \text{Int}(S, R) \), consists of all polynomials in \( K[x] \) taking \( S \) to \( R \). The first relevant studies of rings of integer-valued polynomials date back to 1919 and are due to A. Ostrowski [38] and G. Pólya [39]. Since then rings of integer-valued polynomials have been systematically investigated in connection to several areas of mathematics.

When \( S = R \) it is customary to write \( \text{Int}(R) \) instead of the more cumbersome notation \( \text{Int}(R, R) \); in this case, \( \text{Int}(R) \) is simply called the ring of integer-valued polynomials of \( R \). It is clear that \( R[x] \subseteq \text{Int}(R) \subseteq \text{Int}(S, R) \), and it is worth noting that \( \text{Int}(R) = R[x] \) provided that \( R \) is a local integral domain with finite residue field [9, Corollary 2]. In general, the inclusion \( R[x] \subseteq \text{Int}(R) \) is strict. For instance, when \( R = \mathbb{Z} \), one sees that \( \binom{x}{2} \) belongs to \( \text{Int}(\mathbb{Z}) \) even though it does not belong to \( \mathbb{Z}[x] \); moreover, for every \( n \in \mathbb{N}_0 \),

\[
\binom{x}{n} := \frac{x(x-1) \cdots (x-(n-1))}{n!} \in \text{Int}(\mathbb{Z}),
\]

where we assume the convention that \( \binom{x}{0} = 1 \). The ring \( \text{Int}(\mathbb{Z}) \) exhibits a rather fascinating algebro-combinatorial behavior. It is a free \( \mathbb{Z} \)-module with regular basis \( \{ \binom{x}{n} \mid n \in \mathbb{N}_0 \} \). Indeed, if we set \( \Delta f(k) = f(k+1) - f(k) \), then the Gregory-Newton formula allows us to write any polynomial \( f(x) \) in \( \text{Int}(\mathbb{Z}) \) as a unique \( \mathbb{Z} \)-linear combination of the \( \binom{x}{n} \)'s as follows:

\[
f(x) = \sum_{j=0}^{n} \Delta^{j} f(0) \binom{x}{j}, \tag{1.1}
\]

where \( n \) is the degree of \( f(x) \). This property can be generalized to intermediate rings of the extension \( R[x] \subseteq \text{Int}(\mathbb{Z}, R) \) for any integral domain \( R \) of characteristic zero (see [11, Proposition II.1.4]). From the ring-theoretical viewpoint, it is worth mentioning that \( \text{Int}(\mathbb{Z}) \) is a two-dimensional completely integrally closed Prüfer domain (see [12, Theorems 13 and 17] and [1, Example 2.7(b)]) that is not a Bezout domain. In addition, \( \text{Int}(\mathbb{Z}) \) is one of the most natural examples of non-Noetherian integral domains (see [12, Proposition 3]).

Several aspects of factorizations into irreducibles in rings of integer-valued polynomials have been studied by various authors in the past. For instance, the atomicity of \( \text{Int}(S, R) \) was considered by D. F. Anderson et al. in [6]. In addition, the elasticity of \( \text{Int}(S, R) \) was first investigated by P. J. Cahen and J. L. Chabert in [10], and further studied by S. T. Chapman et al. in [6, 14, 15]. On the other hand, the irreducibility in \( \text{Int}(S, R) \) has been recently studied by S. Frisch and S. Nakato in [23, 37]. Finally, the system of sets of lengths of rings of integer-valued polynomials was investigated by S. Frisch, S. Nakato, and R. Rissner in [22, 24]. In this paper, we continue the study of the atomic structure.
DIVISIBILITY IN RINGS OF INTEGER-VALUED POLYNOMIALS

of rings of integer-valued polynomials, emphasizing on properties that can be defined in terms of divisibility by irreducibles.

Following P. M. Cohn [18], we say that the integral domain \( R \) is atomic if every nonzero nonunit element of \( R \) factors into irreducibles. Also, if every ascending chain of principal ideals of \( R \) has finite length, \( R \) is said to satisfy the ACCP (ascending chain condition on principal ideals). It is easy to verify that every integral domain satisfying the ACCP is atomic. Although the converse of this statement does not hold in general, examples witnessing this failure are hard to come by: the first of such examples was constructed back in the seventies by A. Grams in [32]. In Section 3, we use Grams’ example to construct a class of atomic rings of integer-valued polynomials that do not satisfy the ACCP.

Following A. Grams and H. Warner [33], we say that an integral domain \( R \) is irreducible-divisor-finite (or an idf-domain) provided that every nonzero element of \( R \) has only finitely many non-associate irreducible divisors. In [1], D. D. Anderson, D. F. Anderson, and M. Zafrullah reserved the term finite factorization domain (FFD) for an integral domain that is atomic and an idf-domain simultaneously: they proved indeed that an atomic domain is an FFD if and only if each of its elements has finitely many factorizations into irreducibles.

In Section 4, we establish the following characterization: for any integral domain \( R \) and any infinite subset \( S \) of \( R \), the ring \( \text{Int}(S, R) \) is an FFD if and only if \( R \) is an FFD. In particular, \( \text{Int}(R) \) is an FFD if and only if \( R \) is an FFD. Cohen-Kaplansky domains (CKD) are atomic domains containing only finitely many irreducibles up to associates. Clearly, every CKD is an FFD. We briefly show at the end of Section 4 that no ring of integer-valued polynomials is a CKD.

In Section 5, we keep on investigating divisibility by irreducibles in rings of integer-valued polynomials. The question of whether the polynomial ring \( R[\overline{x}] \) is an idf-domain when \( R \) is an idf-domain was posed by Anderson, Anderson, and Zafrullah [1, Question 2] back in 1990. Even though their paper has been highly cited since then, the question remained open for almost two decades: it was not until 2009 that P. Malcolmson and F. Okoh [36, Theorem 2.5] constructed the first class of counterexamples. The parallel question for rings of integer-valued polynomials goes as follows.

**Question 1.1.** For an integral domain \( R \), is \( \text{Int}(R) \) an idf-domain provided that \( R \) is an idf-domain?

We will show that, as the parallel question for polynomial rings, Question 1.1 has a negative answer; this is the main result we establish in Section 5. As we mentioned before, if \( R \) is an FFD, then so is \( \text{Int}(R) \). Based on this result, we find interesting the fact that neither being atomic nor being an idf-domain transfers from \( R \) to \( \text{Int}(R) \) (this is also known for polynomial rings). We also study rings of integer-valued polynomials where every nonzero nonunit has an irreducible divisor. Honoring H. Furstenberg and following P. Clark’s terminology [16], we say that an integral domain is a Furstenberg domain if every nonzero nonunit has an irreducible divisor. It is clear that every atomic domain is a Furstenberg
domain. We will show that \( \text{Int}(S, R) \) is a Furstenberg domain if and only if \( R \) is a Furstenberg domain (regardless of the cardinality of \( S \)), and this will allow us to provide examples of non-atomic rings of integer-valued polynomials that are Furstenberg domains.

2. Preliminary

In this section, we briefly review most of the notation and terminology we will be using later as well as some of the fundamental results we need from non-unique factorization theory and rings of integer-valued polynomials. See [26] by A. Geroldinger and F. Halter-Koch for an extensive treatment of non-unique factorization theory and [11] by P. J. Cahen and J. L. Chabert for a comprehensive background on integer-valued polynomials.

2.1. General notation. As it is customary, \( \mathbb{Z} \), \( \mathbb{Q} \), \( \mathbb{R} \), and \( \mathbb{C} \) will denote the set integers, rational numbers, real numbers, and complex numbers, respectively. We let \( \mathbb{N} \) and \( \mathbb{N}_0 \) denote the set of positive and nonnegative integers, respectively. In addition, the set of primes will be denoted by \( \mathbb{P} \). For \( p \in \mathbb{P} \) and \( n \in \mathbb{N} \), we let \( \mathbb{F}_{p^n} \) be the finite field of cardinality \( p^n \). If \( P \) is a partially ordered set and \( a, b \in P \), then the interval from \( a \) to \( b \) in \( P \) is the subset \( [a, b] := \{ x \in P \mid a \leq x \leq b \} \) of \( P \). When the partially ordered set is \( \mathbb{Z} \), we denote the interval from \( a \) to \( b \) by \( [a, b] \), reserving the standard single-bracket notation for intervals in the poset \( \mathbb{R} \). In addition, for \( S \subseteq \mathbb{R} \) and \( r \in \mathbb{R} \), we set \( S_{\geq r} = \{ s \in S \mid s \geq r \} \) and \( S_{> r} = \{ s \in S \mid s > r \} \).

2.2. Factorizations. Although a monoid is usually defined to be a semigroup with an identity element, here we will tacitly assume that all monoids are cancellative and commutative. Let \( M \) be a monoid. We say that \( M \) is torsion-free provided that for all \( a, b \in M \), if \( a^n = b^n \) for some \( n \in \mathbb{N} \), then \( a = b \). The quotient group \( \text{gp}(M) \) of \( M \) is the unique abelian group \( \text{gp}(M) \) up to isomorphism satisfying that any abelian group containing a homomorphic image of \( M \) will also contain a homomorphic image of \( \text{gp}(M) \). The rank of \( M \) is the rank of \( \text{gp}(M) \) as a \( \mathbb{Z} \)-module. The group of invertible elements of \( M \) is denoted by \( \mathscr{U}(M) \). We set \( M_{\text{red}} = M / \mathscr{U}(M) \), and we say that \( M \) is reduced if \( |\mathscr{U}(M)| = 1 \), in which case, \( M \) is naturally isomorphic to \( M_{\text{red}} \). For \( a, b \in M \), we say that \( a \) divides \( b \) in \( M \) and write \( a \mid_M b \) if \( b \in aM \). The monoid \( M \) is a valuation monoid if for every \( a, b \in M \) either \( a \mid_M b \) or \( b \mid_M a \). In addition, a submonoid \( N \) of \( M \) is divisor-closed provided that, for any \( a \in M \) and \( b \in N \), the relation \( a \mid_M b \) implies that \( a \in N \).

An element \( a \in M \setminus \mathscr{U}(M) \) is an irreducible (or an atom) if whenever \( a = uv \) for some \( u, v \in M \), then either \( u \in \mathscr{U}(M) \) or \( v \in \mathscr{U}(M) \). The set of irreducibles of \( M \) is denoted by \( \mathscr{A}(M) \). The monoid \( M \) is atomic if every non-invertible element factors into irreducibles. A subset \( I \) of \( M \) is an ideal of \( M \) provided that \( IM = I \) (or, equivalently, \( IM \subseteq I \)). The ideal \( I \) is principal if \( I = bM \) for some \( b \in M \). The monoid \( M \) satisfies the ascending chain condition on principal
ideals (ACCP) if every ascending chain of principal ideals of \( M \) stabilizes. Although it is easy to check that every monoid satisfying the ACCP is atomic, the converse does not hold even for rank-one monoids (see Gram’s monoid in (3.1)). If \( M \) satisfies the ACCP, then every submonoid \( N \) of \( M \) with \( \mathcal{U}(N) = \mathcal{U}(M) \cap N \) satisfies the ACCP. The same does not hold for atomicity (see (3.1)). Clearly, \( M \) is atomic (resp., satisfies the ACCP) if and only if \( M_{\text{red}} \) is atomic (resp., satisfies the ACCP).

Let \( Z(M) \) denote the free (commutative) monoid on \( \mathcal{A}(M_{\text{red}}) \), and let
\[
\pi : Z(M) \rightarrow M_{\text{red}}
\]
be the unique monoid homomorphism fixing \( a \) for every \( a \in \mathcal{A}(M_{\text{red}}) \). If \( z = a_1 \cdots a_\ell \in Z(M) \), where \( a_1, \ldots, a_\ell \in \mathcal{A}(M_{\text{red}}) \), then \( \ell \) is the length of \( z \) and is denoted by \( |z| \). For each \( b \in M \), we set
\[
Z(b) := Z_{M}(b) := \pi^{-1}(b\mathcal{U}(M)).
\]
If \( |Z(b)| = 1 \) for every \( b \in M \), then \( M \) is called a unique factorization monoid (UFM). On the other hand, if \( M \) is atomic and \( |Z(b)| < \infty \) for every \( b \in M \), then \( M \) is called a finite factorization monoid (FFM). Clearly, every UFM is an FFM. The monoid \( M \) is an FFM if and only if every element of \( M \) is contained in only finitely many principal ideals [34, Theorem 2]. If \( M \) is an FFM, then it is not hard to argue that every submonoid \( N \) of \( M \) with \( \mathcal{U}(N) = \mathcal{U}(M) \cap \text{gp}(N) \) is also an FFM. Now, for each \( b \in M \), we set
\[
L(b) := L_{M}(b) := \{|z| \mid z \in Z(b)\}.
\]
If \( M \) is atomic and \( |L(b)| < \infty \) for every \( b \in M \), then \( M \) is called a bounded factorization monoid (BFM). It is clear that if a monoid is an FFM, then it is a BFM. In addition, every BFM satisfies the ACCP [26, Corollary 1.4.4]. As for the ACCP, if \( M \) is a BFM, then it is not hard to verify that every submonoid \( N \) of \( M \) with \( \mathcal{U}(N) = \mathcal{U}(M) \cap N \) is also a BFM.

Let \( R \) be an integral domain. Throughout this paper, we let \( R^* := R \setminus \{0\} \) and \( \text{qf}(R) \) denote the multiplicative monoid and the quotient field of \( R \), respectively. In addition, the group of divisibility of \( R \), often written additively and denoted by \( G(R) \), is the abelian group \( \text{qf}(R)^\times / R^\times \). The group \( G(R) \) is partially ordered by the relation \( xR^\times \leq yR^\times \) if and only if \( y/x \in R \). As for monoids, we let \( \mathcal{A}(R) \) denote the set of irreducibles of \( R \). Following J. Coykendall, D. E. Dobbs, and B. Mullins [19], we say that an integral domain is antimatter if it does not contain any irreducibles. On the other hand, an integral domain is atomic provided that \( R^* \) is an atomic monoid. It is not hard to verify that \( R \) is atomic if and only if the nonnegative cone of \( G(R) \) is atomic.

Each factorization property previously introduced for an atomic monoid can be naturally defined for an integral domain via its multiplicative monoid. We say that \( R \) is a unique (resp., finite, bounded) factorization domain provided that \( R^* \) is a unique (resp., finite, bounded) factorization monoid. Accordingly, we use the acronyms UFD, FFD, and BFD. Observe that this new definition of a UFD coincides with the standard definition of a UFD. We set \( Z(R) := Z(R^*) \)
and, for every $x \in R^*$, we set $Z(x) := Z_{R^*}(x)$ and $L(x) := L_{R^*}(x)$. It is easy to see that $R$ is a BFD if and only if $G(R)$ is a BFM, while $R$ is an FFD if and only if the interval $[R^\times, xR^\times]$ is finite for every positive element $xR^\times \in G(R)$ [5, Theorem 1].

2.3. Polynomial-like rings. Let $R$ be an integral domain with quotient field $K$, and let $S$ be a subset of $R$. The ring of integer-valued polynomials of $R$ on $S$, denoted by $\text{Int}(S, R)$, is the subring of $K[x]$ consisting of all polynomials $p(x)$ satisfying that $p(S) \subseteq R$, that is,

$$\text{Int}(S, R) := \{p(x) \in K[x] \mid p(S) \subseteq R\}.$$ 

When $S = R$, it is customary to write $\text{Int}(R)$ instead of $\text{Int}(S, R)$ and simply call $\text{Int}(R)$ the ring of integer-valued polynomials of $R$. It immediately follows from [9, Corollary 2] that if $R$ is an integral domain containing an infinite field, then the equality $\text{Int}(R) = R[x]$ holds. We record this result here for future reference.

**Theorem 2.1.** If $R$ is an integral domain containing an infinite field, then $\text{Int}(R) = R[x]$.

From the fact that $R^*$ is a divisor-closed submonoid of $\text{Int}(S, R)^*$, it follows that $\text{Int}(S, R)^* = R^\times$. In addition, $\text{Int}(S, R)$ satisfies the ACCP (resp., is a BFD) if and only if $R$ satisfies the ACCP (resp., is a BFD) and $|S| = \infty$ (see Theorem 3.3 and Proposition 4.2), and the same statement holds for the finite factorization property, as we will find in Theorem 4.6. A similar statement does not hold, however, for the property of being atomic, and we will say more about this in the next section.

To construct various examples of rings of integer-valued polynomials here, we use monoid rings with rational exponents. For a monoid $M$, let $R[y; M]$ denote the ring of polynomial expressions with coefficients in $R$ and exponents in $M$. If the monoid $M$ is totally ordered (i.e., it has a total order relation $\leq$ compatible with its operation), then a polynomial expression $\sum_{i=1}^n c_i y^{m_i} \in R[y; M]$ is said to be written canonically if $c_1, \ldots, c_n \in R^\times$ and $m_1 > \cdots > m_n$. It follows from [27, Theorem 8.1] that when $M$ is torsion-free, $R[y; M]$ is an integral domain, in which case, [27, Theorem 11.1] guarantees that $R[y; M]^\times = \{uy^m \mid u \in R^\times$ and $m \in \mathcal{M}(M)\}$. In [27], R. Gilmer gives a generous overview of the advances in monoid rings until 1984. Factorization-theoretical aspects of monoid rings with rational exponents have been recently considered in [30].

3. Atomicity and the ACCP

Rings of integer-valued polynomials are not, in general, atomic. Perhaps the simplest example of a non-atomic ring of integer-valued polynomials is $\text{Int}([0], \mathbb{Z}) = \mathbb{Z} + x\mathbb{Q}[x]$; indeed, one can readily check that $x$ does not factor into irreducibles in $\text{Int}([0], \mathbb{Z})$. This result is generalized in [6] as follows.
Proposition 3.1. [6, Proposition 1.1] Let \( R \) be an integral domain that is not a field, and let \( S \) be a nonempty subset of \( R \). If \( \text{Int}(S, R) \) is atomic, then \( |S| = \infty \).

When \( |S| < \infty \) we can obtain, as a consequence of Proposition 3.1, the following characterizations of the UFDs \( \text{Int}(S, R) \) in terms of the weaker factorization properties we consider in this paper.

Corollary 3.2. Let \( R \) be an integral domain, and let \( S \) be a finite subset of \( R \). Then the following conditions are equivalent.

(a) \( \text{Int}(S, R) \) is a UFD.
(b) \( \text{Int}(S, R) \) is an FFD.
(c) \( \text{Int}(S, R) \) is a BFD.
(d) \( \text{Int}(S, R) \) is atomic.
(e) \( R \) is a field.

Proof. (a) \( \Rightarrow \) (b) \( \Rightarrow \) (c) \( \Rightarrow \) (d): These implications are obvious.

d) \( \Rightarrow \) (e): This follows immediately from Proposition 3.1.

e) \( \Rightarrow \) (a): It is clear that if \( R \) is a field, then \( \text{Int}(S, R) = R[x] \), and so it is a UFD. \( \square \)

In light of Corollary 3.2, in order to study the arithmetic of factorizations of rings of integer-valued polynomials \( \text{Int}(S, R) \), it suffices to focus on the cases where \( |S| = \infty \). We will do this throughout the current section and the next one.

The ascending chain condition on principal ideals. It also follows from Proposition 3.1 that if a ring of integer-valued polynomials \( \text{Int}(S, R) \) satisfies the ACCP, then \( |S| = \infty \). Rings of integer-valued polynomials satisfying the ACCP have been characterized in [10] and [6] in the following way.

Theorem 3.3. Let \( R \) be an integral domain. Then the following statements hold.

1. [10, Theorem 1.3] \( \text{Int}(R) \) satisfies the ACCP if and only if \( R \) satisfies the ACCP.

2. [6, Theorem 1.2] If \( S \) is an infinite subset of \( R \), then \( \text{Int}(S, R) \) satisfies the ACCP if and only if \( R \) satisfies the ACCP.

Unfortunately, none of the statements in Theorem 3.3 hold if we replace the ACCP by atomicity, as we proceed to argue.

Remark 3.4. By Theorem 2.1, the equality \( \text{Int}(R) = R[x] \) holds when \( R \) contains an infinite field. On the other hand, it follows from [40, Example 5.1] that every field can be embedded into an atomic domain \( R \) satisfying that \( R[x] \) is not atomic. As a result, atomicity does not always transfer from an integral domain \( R \) to \( \text{Int}(R) \).\(^1\)

\(^1\)The parallel question of whether atomicity transfers from a monoid \( M \) to a monoid ring \( F[t; M] \) over a given field \( F \) was recently answered negatively in [20].
As we have emphasized before, although not every atomic domain satisfies the ACCP, the search for atomic domains without the ACCP has proved to be a notoriously difficult task. The first of such integral domains was constructed in the seventies by Grams in [32], and not many more constructions of this kind seem to have appeared in the literature since then, with the exceptions of [40, 42] and, more recently, [8, 31]. Here we consider polynomial rings with coefficients in the non-ACCP atomic domain constructed by Grams to obtain a class of atomic rings of integer-valued polynomials that do not satisfy the ACCP. The key ingredient in Grams’ construction is an additive submonoid of \( \mathbb{Q}_{\geq 0} \), which we introduce in the next example. The atomicity of additive sub-monoids of \( \mathbb{Q}_{\geq 0} \) has been systematically investigated during the last few years (see the recent survey [13] and references therein). As we will confirm here, these monoids are effective to find counterexamples in commutative ring theory (see also [20]).

Example 3.5. Let \( (p_n)_{n \in \mathbb{N}} \) be the strictly increasing sequence whose terms are the odd primes, and consider the following additive submonoid of \( \mathbb{Q}_{\geq 0} \):

\[
M := \left\langle \frac{1}{2^n p_n} \mid n \in \mathbb{N}_0 \right\rangle. \tag{3.1}
\]

It is not hard to argue that \( M \) is an atomic monoid with

\[
a(M) = \left\{ \frac{1}{2^n p_n} \mid n \in \mathbb{N}_0 \right\}.
\]

In addition, \( M \) does not satisfy the ACCP because the ascending chain of principal ideals \( \left( \frac{1}{2^n} + M \right)_{n \in \mathbb{N}} \) does not stabilize.

Now let \( F \) be a field, and let \( R \) be the integral domain we obtain after localizing the monoid ring \( F[t; M] \) at the multiplicative set

\[
S := \{ f(t) \in F[t; M] \mid f(0) \neq 0 \}, \tag{3.2}
\]

where \( M \) is the monoid in Example 3.5. It follows from [32, Theorem 1.3] that \( R \) is atomic, and because \( M \) does not satisfy the ACCP, \( R \) cannot satisfy the ACCP. The integral domain \( R \) is the non-ACCP atomic domain constructed by Grams in [32] to disprove Cohn’s assertion [18, Proposition 1.1] that atomicity and the ACCP are equivalent conditions in the setting of integral domains. Honoring Grams, we call \( R \) the Grams’ ring over \( F \). We are now in a position to provide a class of atomic rings of integer-valued polynomials that do not satisfy the ACCP.

Proposition 3.6. Let \( F \) be a field, and let \( R \) be the Grams’ ring over \( F \). If \( |F| = \infty \) (in particular, if \( F \) has characteristic zero), then \( \text{Int}(R) = R[x] \) is an atomic domain that does not satisfy the ACCP.

Proof. Let \( M \) and \( S \) be as in (3.1) and (3.2), respectively, and let \( N \) be the sub-monoid \( \left\langle \frac{1}{2^n} \mid n \in \mathbb{N} \right\rangle \) of \( M \). Observe that \( N \) is a valuation monoid and, therefore,
for any $q_1, q_2 \in N$ the conditions $q_1 \leq q_2$ and $q_1 \mid_N q_2$ are equivalent. It follows from [32, Lemma 1.1] that every element $b \in M$ can be uniquely written as

$$b = \nu(b) + \sum_{i=0}^{k} c_i \frac{1}{2^{j} p_i},$$

where $\nu(b) \in N$ and $c_i \in [0, p_i - 1]$ for every $i \in [0, k]$. Now we define the map $\tilde{\nu} : F[t; M]^* \to N$ by $\tilde{\nu} : \sum_{i=1}^{n} c_i t^{b_i} \mapsto \min\{\nu(b_i) \mid i \in [1, n]\}$ for any canonically-written nonzero polynomial expression $\sum_{i=1}^{n} c_i t^{b_i}$.

As $|F| = \infty$, Theorem 2.1 guarantees that $\text{Int}(R) = R[x]$. Since $R^*$ is a divisor-closed submonoid of $\text{Int}(R)^*$ that does not satisfy the ACCP, $\text{Int}(R)$ cannot satisfy the ACCP. Therefore we are done once we argue that $R[x]$ is atomic. To do this, take a nonzero nonunit $p(x) := \sum_{i=0}^{n} f_i(t)x^i$ in $R[x]$. After replacing $p(x)$ by one of its associates, we can assume that $f_i(t) \in F[t; M]$ for every $i \in [0, n]$. For each $i \in [0, n]$, the fact that $N$ is a valuation monoid ensures that $f_i(t)/f_i^{\kappa(f_i)} \in R$, and it is proved in [32, Theorem 1.3] that $L_R(f_i(t)/f_i^{\kappa(f_i)})$ is bounded. Now set

$$q := \min\{\tilde{\nu}(f_i) \mid i \in [0, n]\} \in N$$

and take $s \in [0, n]$ such that $\tilde{\nu}(f_s) = q$. Once again the fact that $N$ is a valuation monoid allows us to write $p(x) = t^q p'(x)$ for some $p'(x) \in R[x]$. Since the monomials in $F[t; M]$ that are irreducibles remain irreducibles in $R$, the fact that $M$ is atomic ensures that $t^q$ factors into irreducibles in $R$, and so in $R[x]$. To argue that $p'(x)$ also factors into irreducibles in $R[x]$, write $p'(x) = a_1 \cdots a_k b_1(x) \cdots b_\ell(x)$ for some nonunits $a_1, \ldots, a_k \in R$ and some polynomials $b_1(x), \ldots, b_\ell(x) \in R[x]$ with $\deg b_i(x) \geq 1$ for every $i \in [1, \ell]$. Because the coefficient $f_s(t)/t^q$ of $x^s$ has a bounded set of lengths in $R$, and the inequality $k + \ell \leq \max L_R(f_i(t)/t^q) + \deg p'(x)$ holds, we can assume that $k + \ell$ was taken as large as it could possibly be. This guarantees that $a_1 \cdots a_k b_1(x) \cdots b_\ell(x)$ is a factorization of $p'(x)$ in $R[x]$. Hence $R[x]$ is atomic.

We conclude this section with a few words about hereditary atomicity. Following J. Coykendall, F. Gotti, and R. Hasenauer [21], we say that an integral domain $R$ is hereditarily atomic provided that every subring of $R$ is atomic. In particular, every hereditarily atomic domain must be atomic. As for atomicity (and in contrast to Theorem 3.3), it is not true that $\text{Int}(S, R)$ is hereditarily atomic when $R$ is hereditarily atomic and $|S| = \infty$.

**Example 3.7.** If $K$ is a finite algebraic extension of $\mathbb{Q}$, then it follows from [28, Theorem] that every subring of $K$ is Noetherian. Since every Noetherian domain is a BFD [1, Proposition 2.2], the field $K$ is hereditarily atomic. In addition, since $K$ is a field, $\text{Int}(S, K) = K[x]$ for every nonempty subset $S$ of $K$. However, $\text{Int}(S, K)$ is not hereditarily atomic because $K[x]$ contains an isomorphic copy of the integral domain $\mathbb{Z} + x\mathbb{Q}[x]$, which we have seen before that this is not atomic.
However, there are rings of integer-valued polynomials that are hereditarily atomic. The following example sheds some light upon this observation.

**Example 3.8.** Consider the ring of polynomials \( \mathbb{F}_2[x, y] \), where \( \mathbb{F}_2 \) is the field consisting of two elements. Observe that \( \mathbb{F}_2[x, y] \) satisfies the ACCP because it is a UFD. Thus, it follows from Theorem 3.3 that \( \text{Int}(\mathbb{F}_2[x], \mathbb{F}_2[x, y]) \) satisfies the ACCP. Now the fact that the group of units of \( \text{Int}(\mathbb{F}_2[x], \mathbb{F}_2[x, y]) \) is trivial guarantees that every subring of \( \text{Int}(\mathbb{F}_2[x], \mathbb{F}_2[x, y]) \) satisfies the ACCP and is, therefore, atomic. Hence \( \text{Int}(\mathbb{F}_2[x], \mathbb{F}_2[x, y]) \) is hereditarily atomic.

## 4. The bounded and finite factorization properties

In this section, we turn our attention to the bounded and finite factorization properties in rings of integer-valued polynomials. Some special cases of these properties are also considered.

### 4.1. The bounded factorization property

According to [2, Corollary 7.6], for an integral domain \( R \), the ring of integer-valued polynomials \( \text{Int}(R) \) is a BFD if and only if \( R \) is a BFD. We begin this section with a mild generalization of this property, mirroring part (2) of Theorem 3.3. We need the following technical lemma, which we have borrowed from [11, Proposition I.3.1], where the reader can find the proof.

**Lemma 4.1.** Let \( R \) be an integral domain, and let \( S \) be an infinite subset of \( R \). Then there exists a sequence \( (d_n)_{n \in \mathbb{N}_0} \) whose terms are nonzero elements of \( R \) satisfying that \( d_n f(x) \in R[x] \) for every \( f(x) \in \text{Int}(S, R)^* \) with \( \deg f(x) = n \).

**Proposition 4.2.** Let \( R \) be an integral domain, and let \( S \) be an infinite subset of \( R \). Then \( \text{Int}(S, R) \) is a BFD if and only if \( R \) is a BFD.

**Proof.** Because \( \text{Int}(S, R)^{\times} \cap R = R^{\times} \), the ring \( R \) is a BFD provided that \( \text{Int}(S, R) \) is a BFD, and so the direct implication follows. For the reverse implication, suppose that \( R \) is a BFD and set \( K := \text{qf}(R) \). By virtue of Lemma 4.1, there is a sequence \( (d_n)_{n \in \mathbb{N}_0} \) whose terms are nonzero elements of \( R \) such that \( d_n f(x) \in R[x] \) for every \( f(x) \in \text{Int}(S, R)^* \) with \( \deg f(x) \leq n \). Now since

\[
R[x] \subseteq \text{Int}(S, R) \subseteq R + xK[x],
\]

it follows from [2, Theorem 7.5] that \( \text{Int}(S, R) \) is also a BFD. \( \square \)

**Corollary 4.3.** [2, Corollary 7.6] For an integral domain \( R \), the ring \( \text{Int}(R) \) is a BFD if and only if \( R \) is a BFD.

**Proof.** If \( |R| = \infty \), then the corollary is a special case of Proposition 4.2. Suppose, on the other hand, that \( |R| < \infty \). In this case, \( R \) is a (finite) field and, therefore, \( \text{Int}(R) = R[x] \) is a UFD. Hence both \( \text{Int}(R) \) and \( R \) are BFDs. \( \square \)
We observe that the assumption \(|S| = \infty\) is required to guarantee that the direct implication of Proposition 4.2 holds. Indeed, although \(\mathbb{Z}\) is a BFD, we have seen before that \(\text{Int}(\emptyset, \mathbb{Z}) = \mathbb{Z} + \mathbb{Q}[x]\) is not even atomic.

Theorem 3.3 and Proposition 4.2, used in tandem, allow us to construct rings of integer-valued polynomials that satisfy the ACCP but are not BFDs.

**Example 4.4.** For a field \(F\), consider the monoid ring \(R := F[y; M]\), where \(M\) is the additive submonoid \(\{1/p \mid p \in \mathbb{P}\}\) of \(\mathbb{Q}\). It was argued in [1, Example 2] that \(R\) satisfies the ACCP but is not a BFD. In light of Theorem 3.3 and Proposition 4.2, for any infinite subset \(S\) of \(R\), we obtain that \(\text{Int}(S, R)\) satisfies the ACCP but is not a BFD.

A special class consisting of BFDs is that of half-factorial domains. Following A. Zaks [41], we say that an integral domain \(R\) is a half-factorial domain (HFD) if \(R\) is atomic and every two factorizations of the same element of \(R\) have the same length. Unlike the properties of satisfying the ACCP and being a BFD, being an HFD does not transfer from an integral domain to its ring of integer-valued polynomials.

**Example 4.5.** Since \(\mathbb{Z}\) is a UFD, it is also an HFD. It is not hard to verify that \(\binom{n}{k}\) is an irreducible polynomial in \(\text{Int}(\mathbb{Z})\) for every \(n \in \mathbb{N}\) (see [12, Proposition 6]). The identity \(2 \cdot 3 \cdot \binom{6}{3} = (x - 5) \cdot \binom{5}{3}\) clearly holds, and its sides yield factorizations of the integer-valued polynomial \(p(x) = 6\binom{3}{6}\). As a result, \(\{2, 3\} \subseteq \text{L}(p(x))\), which implies that \(\text{Int}(\mathbb{Z})\) is not an HFD. Thus, there are rings of integer-valued polynomials that are BFDs but not HFDs (\(\text{Int}(\mathbb{Z})\) is a BFD by Proposition 4.2). We emphasize that \(\text{Int}(\mathbb{Z})\) has infinite elasticity, a property that is significantly stronger than that of failing half-factoriality (see [10, Theorem 1.6] for details).

Example 4.5 also illustrates that being a UFD does not transfer, in general, from an integral domain to its ring of integer-valued polynomials.

### 4.2. The finite factorization property.

Now we turn our attention to the finite factorization property. In the next theorem, we provide an analog of Theorem 3.3 and Proposition 4.2.

**Theorem 4.6.** Let \(R\) be an integral domain, and let \(S\) be an infinite subset of \(R\). Then \(\text{Int}(S, R)\) is an FFD if and only if \(R\) is an FFD.

**Proof.** For the direct implication, let us assume that \(\text{Int}(S, R)\) is an FFD. Since \(\text{Int}(S, R)^{\infty} = R^{\infty}\), we see that \(\text{Int}(S, R)^{\infty} \cap \mathfrak{q}(R) = R^{\infty}\). This, together with the assumption that \(\text{Int}(S, R)\) is an FFD, ensures that \(R\) is also an FFD.

For the reverse implication, let us assume that \(R\) is an FFD. Since \(|S| = \infty\), Lemma 4.1 guarantees the existence of a sequence \((d_n)_{n \in \mathbb{N}_+}\) whose terms are nonzero elements of \(R\) such that \(d_nf(x) \in R[x]\) for all \(f(x) \in \text{Int}(S, R)^{\infty}\) with \(\deg f(x) = n\). Fix an algebraic closure \(F\) of the field \(\mathfrak{q}(R)\). Now take a nonzero polynomial \(p(x) \in \text{Int}(S, R)\) with degree \(n\), and let us argue that \(\mathbb{Z}_{\text{Int}(S, R)}(p(x))\).
contains finitely many polynomials up to associates in \( \text{Int}(S, R) \). Assume, on the other hand, that \( n \geq 1 \). Let \( c_p \) be the leading coefficient of \( p(x) \), and then write \( p(x) = c_p \prod_{i=1}^{n}(x - r_i) \) for some \( r_1, ..., r_n \in F \). As \( \text{deg } p(x) = n \), the polynomial \( d_n p(x) \) belongs to \( R[x] \) and, in particular, \( d_n c_p \in R \). Proving that \( p(x) \) has only finitely many factorizations in \( \text{Int}(S, R) \) amounts to showing that, for each \( J \subseteq [1, n] \), the set

\[
D_J := \{ q(x) := c_q \prod_{j \in J}(x - r_j) \in \text{Int}(S, R) \mid q(x) \text{ divides } p(x) \text{ in } \text{Int}(S, R) \}
\]

contains finitely many polynomials up to associates in \( \text{Int}(S, R) \). Now fix \( J \subseteq [1, n] \), set \( m := |J| \), and let \( q(x) \) be a polynomial in \( D_J \) with leading coefficient \( c_q \). Since \( q(x) \) and \( p(x)/q(x) \) are polynomials in \( \text{Int}(S, R) \) with degrees \( m \) and \( n - m \), respectively, \( d_m c_q \) and \( d_{n-m}(c_p/c_q) \) both belong to \( R \). Let \( G(R) \) be the divisibility group of \( R \), and note that the set

\[
C_m := \{ d_m R^x \in G(R) \mid d_m r \in R \text{ and } d_m r |_{R} d_m d_{n-m}(d_n c_p) \}
\]

is precisely the interval \([R^x, d_m d_{n-m}(d_n c_p) R^x]\) of \( G(R) \). Since \( R \) is an FFD, it follows from [5, Theorem 1] that \( |C_m| < \infty \). From

\[
(d_m c_q)(d_n d_{n-m}(c_p/c_q)) = d_m d_{n-m}(d_n c_p) \in R
\]

and \( d_n d_{n-m}(c_p/c_q) \in R \), we obtain that \( d_m c_q R^x \in C_m \). Consider now the map \( D_J \to C_m \) determined by \( q(x) \mapsto d_m c_q R^x \). Observe that, for \( r, r' \in qf(R)^x \), the equality \( d_m r R^x = d_m r' R^x \) holds if and only if \( r/r' \in R^x \). Hence the map \( D_J/R^x \to C_m \) is well-defined and injective, which implies that \( |D_J/R^x| \leq |C_m| < \infty \). Therefore \( p(x) \) has only finitely many non-associate divisors in \( \text{Int}(S, R) \). As a consequence, we conclude that \( \text{Int}(S, R) \) is an FFD.

\textbf{Corollary 4.7.} For an integral domain \( R \), the ring \( \text{Int}(R) \) is an FFD if and only if \( R \) is an FFD.

\textbf{Proof.} When \( |R| = \infty \), this is a special case of Theorem 4.6. Assume, on the other hand, that \( |R| < \infty \). In this case, \( R \) is a field and, therefore, \( \text{Int}(R) = R[x] \) is a UFD. Hence both \( \text{Int}(R) \) and \( R \) are FFDs.

\textbf{Corollary 4.7} allows us to identify rings of integer-valued polynomials that are FFDs but not UFDs.

\textbf{Example 4.8.} We have seen in Example 4.5 that \( \text{Int}(\mathbb{Z}) \) is not even an HFD. However, since \( \mathbb{Z} \) is an FFD, Corollary 4.7 guarantees that \( \text{Int}(\mathbb{Z}) \) is an FFD.

Following D. D. Anderson and B. Mullins [5], we say that an integral domain \( R \) is a \textit{strong finite factorization domain (SFFD)} if every nonzero element of \( R \) has only finitely many divisors. One can verify that an integral domain is an SFFD if and only if it is an FFD with finite group of units (see [5, Theorem 5] for additional characterizations).

\textbf{Corollary 4.9.} Let \( R \) be an integral domain, and let \( S \) be an infinite subset of \( R \). Then \( \text{Int}(S, R) \) is an SFFD if and only if \( R \) is an SFFD.
Proof. The ring \( \text{Int}(S, R) \) is an SFFD if and only if it is an FFD and \( \text{Int}(S, R) \times = R \times \) is finite. In light of Theorem 4.6, this happens if and only if \( R \) is an FFD and \( R \times \) is finite, which is equivalent to the fact that \( R \) is an SFFD.

We are now in a position to exhibit rings of integer-valued polynomials satisfying the bounded factorization property but not the finite factorization property.

Example 4.10. Let \( F \) be a field, and let \( M \) be the additive submonoid \( \{0\} \cup \mathbb{R}_{>1} \) of \( \mathbb{R} \). It follows from [29, Proposition 4.5] that \( M \) is a BFM, and one can readily check that \( \mathcal{M}(M) = \{1, 2\} \). Therefore [3, Theorem 13.3] guarantees that the monoid ring \( R := F[y; M] \) is a BFD. On the other hand, \( \{y^n \mid a \in \mathcal{M}(M)\} \subseteq \mathcal{M}(R) \), and so we can infer from the equalities \( y^3 = y^2 + y + 1 \) (for all \( n \in \mathbb{N}_{\geq 3} \)) that \( R \) is not an FFD. Now Proposition 4.2 and Theorem 4.6, used in tandem, allow us to conclude that, for every infinite subset \( S \) of \( R \), the ring of integer-valued polynomials \( \text{Int}(S, R) \) is a BFD that is not an FFD.

The class of FFDs consisting of integral domains with only finitely many irreducibles up to associates has been well investigated. Following D. D. Anderson and J. L. Mott [4], we call such integral domains Cohen-Kaplansky domains (CKD). The terminology is justified by the fact that Cohen-Kaplansky domains were first studied by I. S. Cohen and I. Kaplansky in [17]. Although it follows from Theorem 4.6 that there are plenty of rings of integer-valued polynomials that are FFDs, none of them happens to be a CKD, as the following proposition indicates.

Proposition 4.11. For any integral domain \( R \) and \( S \subseteq R \), the ring \( \text{Int}(S, R) \) is not a CKD.

Proof. Let \( R \) be an integral domain with quotient field \( K \), and let \( S \) be a subset of \( R \). If \( S \) is empty, then \( \text{Int}(S, R) = K[x] \), which contains infinitely many non-associate irreducibles: indeed, if the polynomials \( a_1(x), \ldots, a_k(x) \) were the only irreducibles in \( K[x] \) (up to associates), then the irreducible \( a_1(x) \cdots a_k(x) + 1 \) would be an associate of \( a_i(x) \) for some \( i \in [1, k] \), which is clearly not possible. In addition, observe that if \( R \) is finite, then it is a field and so the equality \( \text{Int}(S, R) = K[x] \) holds once again, whence \( \text{Int}(S, R) \) contains infinitely many non-associate irreducibles. Thus, \( \text{Int}(S, R) \) is not a CKD provided that \( S \) is empty or \( R \) is finite.

Suppose, on the other hand, that \( S \) is not empty and \( R \) is not finite. Fix \( s \in S \) and, for each \( r \in R^\times \), consider the polynomial

\[
a_r(x) = rx - rs + 1 \in \text{Int}(S, R).
\]

We claim that \( a_r(x) \) is irreducible in \( \text{Int}(S, R) \) for all \( r \in R^\times \). To see this, fix \( r \in R^\times \) and write \( a_r(x) = tf(x) \), where \( t \in R \) and \( f(x) \in \text{Int}(S, R) \). Observe that \( t^{-1} = a_r(s)t^{-1} = f(s) \in R \), which means that \( t \in R^\times \). Therefore \( \{a_r(x) \mid r \in R^\times \} \) is an infinite set of irreducibles of \( \text{Int}(S, R) \), and it follows immediately that no
two distinct polynomials of this set can be associates in \( \text{Int}(S, R) \). Thus, we can also conclude in this case that \( \text{Int}(S, R) \) is not a CKD.

As a corollary of the previous proof, we obtain the following corollary.

**Corollary 4.12.** For any integral domain \( R \) and \( S \subseteq R \), the ring \( \text{Int}(S, R) \) is not antimatter.

### 5. On irreducible divisors

In this final section, we study divisibility by irreducibles in rings of integer-valued polynomials. We consider two natural relaxations of atomicity and the finite factorization property: the Furstenberg and the irreducible-divisor-finite properties, respectively.

#### 5.1. Furstenberg domains

Following [16], we say that an integral domain is a **Furstenberg domain** if every nonunit element is divisible by an irreducible. Clearly, every atomic domain is a Furstenberg domain. For an integral domain \( R \) and a subset \( S \) of \( R \), it turns out that \( \text{Int}(S, R) \) is a Furstenberg domain if and only if \( R \) is a Furstenberg domain, regardless of the cardinality of \( S \).

**Proposition 5.1.** Let \( R \) be an integral domain, and let \( S \) be a nonempty subset of \( R \). Then \( \text{Int}(S, R) \) is a Furstenberg domain if and only if \( R \) is a Furstenberg domain.

**Proof.** For the direct implication, suppose that \( \text{Int}(S, R) \) is a Furstenberg domain. Let \( r \) be a nonunit of \( R^* \). Then \( r \notin R^\times = \text{Int}(S, R)^\times \) and, because \( \text{Int}(S, R) \) is a Furstenberg domain, there exists \( a \in \mathcal{A}(\text{Int}(S, R)) \) such that \( a \) divides \( r \) in \( \text{Int}(S, R) \). Since \( R^* \) is a divisor-closed submonoid of \( \text{Int}(S, R)^* \), we see that \( a \in \mathcal{A}(\text{Int}(S, R)) \cap R = \mathcal{A}(R) \). Hence \( R \) is a Furstenberg domain.

To argue the reverse implication, suppose that \( R \) is a Furstenberg domain, and take a nonzero nonunit \( f(x) \in \text{Int}(S, R) \). If \( f(x) \) factors into irreducibles in \( \text{Int}(S, R) \), then it must be divisible by an irreducible. On the other hand, assume that the polynomial \( f(x) \) does not factor into irreducibles in \( \text{Int}(S, R) \). Set \( d := \deg f(x) \) and write \( f(x) = g_1(x) \cdots g_n(x) \) for some nonunits \( g_1(x), \ldots, g_n(x) \) and \( n \in \mathbb{N} \) with \( n > d \). Then there is an \( i \in [1, n] \) such that \( g_i(x) \in R \). Since \( g = g_i(x) \in R \setminus R^\times \), the assumption that \( R \) is a Furstenberg domain guarantees that \( g \) is divisible by some \( a \in \mathcal{A}(R) \). Because \( R^* \) is a divisor-closed submonoid of \( \text{Int}(S, R)^* \), the element \( a \) is also irreducible in \( \text{Int}(S, R) \). Hence \( f(x) \) is divisible by an irreducible in \( \text{Int}(S, R) \). As a result, we can conclude that \( \text{Int}(S, R) \) is a Furstenberg domain.

As an application of Proposition 5.1, we can construct certain new examples of Furstenberg domains. We illustrate this in the next example, where we exhibit non-atomic Furstenberg domains \( \text{Int}(S, R) \) for finite and infinite subsets \( S \) of \( R \). Further examples of non-atomic Furstenberg domains have been given in [35].
Example 5.2. (1) For a nonempty subset $S$ of $\mathbb{Z}$, consider the ring of integer-valued polynomials $\text{Int}(S, \mathbb{Z})$. By Proposition 5.1, the ring $\text{Int}(S, \mathbb{Z})$ is a Furstenberg domain. When $|S| < \infty$, it follows from Proposition 3.1 that $\text{Int}(S, \mathbb{Z})$ is not atomic. On the other hand, when $|S| = \infty$, it follows from Theorem 3.3 that $\text{Int}(S, \mathbb{Z})$ satisfies the ACCP and is, therefore, atomic. Hence $\text{Int}(S, \mathbb{Z})$ is a Furstenberg domain, which is atomic if and only if $|S| = \infty$.

(2) We can use the example in part (1), in tandem with Proposition 5.1, to produce a non-atomic Furstenberg domain $\text{Int}(\bar{\mathcal{A}}; \mathbb{Z})$. To do so, set $\mathcal{A} = \mathbb{Z} + y\mathbb{Q}[y]$, which is precisely the ring of integer-valued polynomials $\text{Int}([0], \mathbb{Z})$ (in the indeterminate $y$). By part (1), $\mathcal{A}$ is a non-atomic Furstenberg domain. Now let $S$ be an infinite subset of $\mathcal{A}$. It follows from Proposition 5.1 that $\text{Int}(S, \mathcal{A})$ is a Furstenberg domain. Finally, the fact that $\mathcal{A}$ is not atomic ensures that $\text{Int}(S, \mathcal{A})$ is not atomic; this is because $\mathcal{A}^\times$ is a divisor-closed submonoid of $\text{Int}(S, \mathcal{A})^\times$. Hence $\text{Int}(S, \mathcal{A})$ is a non-atomic Furstenberg domain with $|S| = \infty$.

There are integral domains that are not Furstenberg domains; for instance, every antimatter domain that is not a field fails to be a Furstenberg domain. Then we can use non-Furstenberg domains and Proposition 5.1 to construct rings of integer-valued polynomials that are not Furstenberg domains. We illustrate this observation in the following example.

Example 5.3. For the monoid ring $R = \mathbb{Z}[y; Q_{>0}]$, consider the ring of integer-valued polynomials $\text{Int}(R)$. Observe that $R$ is not a Furstenberg domain because every nonunit divisor of $y$ in $R$ has the form $\pm y^q$ for some $q \in Q_{>0}$, which is not irreducible as $\pm y^q = \pm (y^{q/2})^2$. Thus, it follows from Proposition 5.1 that $\text{Int}(R)$ is not a Furstenberg domain.

5.2. Irreducible-divisor-finite domains. Following the terminology of [33], we say that an integral domain $R$ is an irreducible-divisor-finite domain (or an idf-domain for short) provided that every nonzero element of $R$ has only finitely many irreducible divisors up to associates. These integral domains were first investigated by Grams and Warner in [33]. As mentioned in the introduction, an integral domain is an FFD if and only if it is an atomic idf-domain [1, Theorem 5.1]. The atomic condition is crucial in the previous statement as, for instance, every antimatter domain (that is not a field) is an idf-domain that is not an FFD.

Similarly, one can drop the atomic condition from the Cohen-Kaplansky property. We say that an integral domain $R$ is an irreducible-finite domain (IFD) provided that $R$ contains only finitely many irreducibles up to associates. Then an integral domain is a CKD if and only if it is an atomic IFD. As the following example shows, there are IFDs that are not CKDs.

Example 5.4. Let $p$ be a prime number, and consider the integral domain $R := \mathbb{Z}_{(p)} + x\mathbb{C}[x]$. As $\mathbb{C}[x]$ is a local domain, it follows from [7, Lemma 4.17] that $R^\times = \mathbb{Z}_p^\times + x\mathbb{C}[x]$, and so no formal power series $f(x)$ in $R$ with $f(0) = 0$
is irreducible because it can be written as \( f(x) = p(f(x)/p) \). Then for any \( q \in \mathbb{Z}_p \) and \( g(x) \in \mathbb{C}[x] \), the element \( q + xg(x) \) belongs to \( \mathcal{A}(R) \) if and only if the \( p \)-adic valuation of \( q \) is 1. Hence \( \mathcal{A}(R) = pR^\times \), which implies that \( R \) is an IFD. Since \( \mathbb{Z}_p \) is not a field, [1, Proposition 1.2] guarantees that \( R \) is not atomic. Thus, \( R \) is not a CKD.

It is clear that every IFD is an idf-domain. Not every idf-domain, however, is an IFD. For instance, \( \mathbb{Z} \) is an atomic idf-domain (FFD) that is not an IFD. Moreover, there are non-atomic idf-domains that are not IFDs. Let us construct one of such integral domains.

**Example 5.5.** Let \( D \) denote the monoid ring \( F_2[y; Q_{\geq 0}] \), and let \( K \) denote the quotient field of \( D \). Now set \( R := D + xK[x] \). Since \( D \) is not a field, it follows from [1, Proposition 1.2] that \( R \) is not atomic. For the rest of our argument, we need the following claim.

**Claim.** If \( a(x) \in \mathcal{A}(R) \), then \( a(0) = 1 \).

**Proof of Claim.** We take \( f(x) \in R^\times \) with \( f(0) \neq 1 \). First, assume that \( f(0) = 0 \). Then \( f(x)/y \in R^\times \). Since the additive monoid \( Q_{\geq 0} \) is reduced, \( R^\times = D^\times = \{1\} \), and so \( y \notin R^\times \). Because both \( y \) and \( f(x)/y \) belong to \( R^\times \setminus R^\times \), the equality \( f(x) = y(f(x)/y) \) ensures that \( f(x) \notin \mathcal{A}(R) \). Now assume that \( f(0) \neq 0 \). If \( \deg f(x) = 0 \), then \( f(x) \notin \mathcal{A}(R) \) because \( D^\times \) is an antimatter divisor-closed submonoid of \( R^\times \). If \( \deg f(x) \geq 1 \), then after writing \( f(x) = f(0)(f(x)/f(0)) \), the fact that both \( f(0) \) and \( f(x)/f(0) \) belong to \( R^\times \setminus R^\times \) ensures that \( f(x) \notin \mathcal{A}(R) \). Thus, the claim is established.

Let us proceed to prove that \( R \) is an idf-domain that is not an IFD. To argue that \( R \) is an idf-domain, fix \( f(x) \in R^\times \). It suffices to observe that for every divisor \( g(x) \) of \( f(x) \) in \( K[x] \), the set \( S := \{ k \in K^\times \mid kg(x) \in \mathcal{A}(R) \} \) is finite: indeed, if \( g(0) = 0 \), then \( S \) is empty, while if \( g(0) \neq 0 \), then \( k = g(0)^{-1} \) by virtue of the claim previously proved. Thus, \( R \) is an idf-domain. To argue that \( R \) is not an IFD, we observe that, since \( D^\times = \{1\} \), the polynomial \( rx + 1 \) is irreducible in \( R \) for each \( r \in D^\times \). As a consequence, \( \{rx + 1 \mid r \in D^\times \} \) is an infinite set consisting of pairwise non-associate irreducible polynomials of \( R \).

The following proposition yields two necessary conditions for rings of integer-valued polynomials to be idf-domains.

**Proposition 5.6.** Let \( R \) be an integral domain, and let \( S \) be a nonempty subset of \( R \) such that \( \text{Int}(S, R) \) is an idf-domain. Then the following statements hold.

1. \( R \) is an idf-domain.

2. If \( |S| < \infty \), then \( R \) is an IFD.

**Proof.** (1) Since \( R^\times \) is a divisor-closed submonoid of \( \text{Int}(S, R)^\times \), the equality \( \mathcal{A}(\text{Int}(S, R)) \cap R = \mathcal{A}(R) \) holds, from which one infers that \( R \) is an idf-domain.

(2) Now suppose that \( |S| < \infty \), and write \( S = \{ s_1, \ldots, s_n \} \). Then set \( f(x) := \prod_{i=1}^n (x - s_i) \). For every nonzero \( r \in R \), it is clear that \( f(x)/r \) belongs to \( \text{Int}(S, R) \)
and, therefore, \( r \) divides \( f(x) \) in \( \text{Int}(S, R) \). Thus, the equality \( \mathcal{A}(\text{Int}(S, R)) \cap R = \mathcal{A}(R) \) guarantees that every irreducible element of \( R \) is an irreducible element of \( \text{Int}(S, R) \) dividing \( f(x) \). Hence the fact that \( \text{Int}(S, R) \) is an idf-domain, along with \( \text{Int}(S, R)^+ = R^+ \), implies that \( R \) is an IFD.

According to part (1) of Proposition 5.6, an integral domain is an idf-domain when its ring of integer-valued polynomials is an idf-domain. We proceed to consider the converse, which was stated as Question 1.1 in the introduction. It turns out that, as it is the case for polynomial rings, the property of being an idf-domain does not transfer from an integral domain to its ring of integer-valued polynomials. We will establish this result in our next theorem, which is the main result we present in this section.

First, we introduce a monoid that is crucial for our construction. If \( T \) is a nonempty subset of \( \mathbb{R} \), then the additive submonoid

\[
\text{cone}_Q(T) := \left\{ \sum_{i=1}^{n} q_i t_i \mid n \in \mathbb{N}, \text{ and } q_i \in \mathbb{Q}_{\geq 0} \text{ and } t_i \in T \text{ for every } i \in [1, n] \right\}
\]

of \( \mathbb{R} \) is called the rational cone of \( T \) over \( \mathbb{Q} \). Submonoids of \( \mathbb{R} \) obtained in this way are called rational cones of \( \mathbb{R} \). Note that rational cones are closed under nonnegative rational multiplication. Let \( t \) be a transcendental number such that \( 0 < t < 1 \), and consider the sequences \((a_n)_{n \in \mathbb{N}}\) and \((b_n)_{n \in \mathbb{N}}\) of positive real numbers defined as follows:

\[
a_n := 1 - t^{n+1} \quad \text{and} \quad b_n := t - t^{n+1}.
\]

Now we consider the monoid

\[
M := \text{cone}_Q(T), \text{ where } T := \{ t^n, a_n, b_n \mid n \in \mathbb{N} \}.
\]

Observe first that \( 1 = a_1 + t^2 \in M \) and also that \( M \) is a reduced monoid. We are in a position to state and prove the main result of this section.

**Theorem 5.7.** For each \( p \in \mathbb{P} \), let \( R \) be the monoid ring \( \mathbb{F}_p[y; M] \), where \( M \) is the monoid in (5.1). Then the following statements hold.

1. \( R \) is antimatter, and so an idf-domain.
2. \( \text{Int}(R) \) is not an idf-domain.

**Proof.** (1) Observe that \( R^+ = \mathbb{F}_p^+ \). To argue that \( R \) is antimatter, take a nonzero \( f(y) \in R \) and write \( f(y) = \sum_{i=1}^{n} y^{m_i} \) for some \( m_1, \ldots, m_n \in M \) (not necessarily distinct). Since \( M \) is a rational cone, \( m_i/p \in M \) for every \( i \in [1, n] \) and, therefore, \( g(y) := \sum_{i=1}^{n} y^{m_i/p} \in R \). Since \( f(y) = g(y)^p \), the polynomial expression \( f(y) \) is not irreducible. Hence \( \mathcal{A}(R) \) is empty, and so \( R \) is antimatter. As a consequence, \( R \) is an idf-domain.

(2) We proceed to prove that \( \text{Int}(R) \) is not an idf-domain. We claim that \( yx + y^t \) has infinitely many non-associate irreducible divisors in \( \text{Int}(R) \). Since \( yx + y^t = y^{m+1}(y^a x + y^b) \), it suffices to show that \( y^a x + y^b \) is irreducible in \( \text{Int}(R) \) for every \( n \in \mathbb{N} \). To do so, fix \( y^a x + y^b \) for some \( i \in \mathbb{N} \). Now observe that
We summarize some of our main results, highlighting their known parallel statements in the context of polynomial rings.
Remark 5.8. Let $R$ be an integral domain. As observed in Remark 3.4, the ring of integer-valued polynomials $\text{Int}(R)$ may not be atomic even when $R$ is atomic. In addition, we have seen in Theorem 5.7 that $\text{Int}(R)$ may not be an idf-domain even when $R$ is an idf-domain. However, it follows from Corollary 4.7 that if $R$ is an atomic idf-domain, then $\text{Int}(R)$ is also an atomic idf-domain (recall that, in light of [1, Theorem 5.1], an integral domain is an atomic idf-domain if and only if it is an FFD). These results resemble nontrivial facts already known for polynomial rings ([1, Proposition 5.3], [36, Theorem 2.5], and [40, Example 5.1]).

Let $R$ be an integral domain, and let $S$ be a subset of $R$. By virtue of part (2) of Proposition 5.6, when $S$ is finite we need $R$ to be an IFD for $\text{Int}(S, R)$ to be an idf-domain. One can naturally wonder for which finite subsets $S$ of $R$ the converse holds, that is, the fact that $R$ is an IFD guarantees that $\text{Int}(S, R)$ is an idf-domain. We conclude this paper by giving a partial answer to this question, and doing so we provide a way to produce rings of integer-valued polynomials that are non-atomic idf-domains.

Theorem 5.9. Let $R$ be an IFD. Then $\text{Int}([s], R)$ is an idf-domain for every $s \in R$.

Proof. Fix $s \in R$, and let $K$ denote the quotient field of $R$. Then set $T := \text{Int}([s], R) = R + (x - s)K[x]$. If $R$ is a field, then $T = K[x]$ is an FFD and, as a consequence, an idf-domain. On the other hand, we assume that $R$ is not a field. Let $f(x)$ be a nonzero nonunit of $T$, and let us argue that the following set is finite:

$$A := \{a(x)T^\times \mid a(x) \in \mathcal{A}(T) \text{ and } a(x) \mid f(x)\}.$$  

First, observe that if $b(s) = 0$ for some nonzero polynomial $b(x)$ in $T$, then we can write $b(x) = r(b(x)/r)$ for some nonzero nonunit $r \in R$ (which must exist because $R$ is not a field), and the fact that $b(x)/r$ is a nonunit of $T$ guarantees that $b(x) \notin \mathcal{A}(T)$. Thus, $s$ is not a root of any irreducible polynomial in $T$. As a consequence, if $a(x) \in \mathcal{A}(T)$ and $\deg a(x) \geq 1$, then the equality $a(x) = a(s)(a(x)/a(s))$ implies that $a(s) \in T^\times$. Let $G(R)$ be the divisibility group of $R$, and write $A = A_0 \cup A_1$, where $A_0 := A \cap G(R)$ and $A_1 := A \setminus A$. As $K^\times$ is a divisorial submonoid of $T^\times$, the equality $\mathcal{A}(T) \cap R = \mathcal{A}(R)$ holds. This, along with the fact that $R$ contains only finitely many irreducibles (up to associates), ensures that $A_0$ is finite. To argue that $A_1$ is also finite, set

$$B := \{b(x)K^\times \mid b(x) \in K[x] \text{ and } b(x) \mid_{K[x]} f(x)\},$$

and consider the map $\varphi : A_1 \to B$ defined by $a(x)T^\times \mapsto a(x)K^\times$. Since $T^\times = R^\times$, the map $\varphi$ is well-defined. Now suppose that $a(x)$ and $a'(x)$ are non-constant polynomials in $\mathcal{A}(T)$ both dividing $f(x)$ in $T$ such that $a(x)K^\times = a'(x)K^\times$. The fact that both $a(s)$ and $a'(s)$ belong to $T^\times$ implies that $a(x)T^\times = a'(x)T^\times$. Hence the map $A_1 \to B$ is injective. Since $K[x]$ is an FFD, the set $B$ is finite. Hence $A_1$ is also finite, and so $A$ is finite. We can now conclude that $T$ is an idf-domain. 

\[\square\]
As a direct consequence of Theorem 5.9 and part (2) of Proposition 5.6, we obtain the following corollary.

**Corollary 5.10.** Let $R$ be an integral domain. For each $s \in R$, the ring $\text{Int}(\{s\}, R)$ is an idf-domain if and only if $R$ is an IFD.

Finally, we observe that Theorem 5.9 cannot be extended to $\text{Int}(S, R)$ for finite subsets $S$ of $R$. The following example, which is a modified version of Theorem 5.7, sheds some light upon this observation.

**Example 5.11.** For $p \in \mathbb{P}$, let $R := \mathbb{F}_p[y; M]$ be the integral domain introduced in Theorem 5.7, where $M$ is the rational cone of the set
\[ T = \{ t^n, 1 - t^{n+1}, t - t^{n+1} \mid n \in \mathbb{N} \} \]
for some fixed transcendental number $t \in (0, 1)$. We have already seen that $R$ is antimatter and, therefore, an IFD. Now consider the ring of integer-valued polynomials $\text{Int}(S, R)$, where $S = \{ 0, 1 \}$. Note that for any polynomial $f(x) := r_1 x + r_0 \in \mathbb{Q}(R)[x]$, the equalities $r_0 = f(0)$ and $r_1 = f(1) - f(0)$ guarantee that $f(x) \in \text{Int}(S, R)$ if and only if $r_0, r_1 \in R$ (as it is the case in Theorem 5.7). Now we can simply follow the lines of Theorem 5.7 to show that $y^{1-r^{n+1}} x + y^{r-r^{n+1}}$ is an irreducible divisor of $y x + y^r$ in $\text{Int}(S, R)$ for every $n \in \mathbb{N}$. As a consequence, we conclude that $\text{Int}(S, R)$ is not an idf-domain even though $R$ is an IFD.

For an integral domain $R$, we have seen that $R$ is an IFD if and only if $\text{Int}(S, R)$ is an idf-domain provided that the set $S$ is a singleton (Corollary 5.10). On the other hand, we have seen that the same property does not hold even for every set $S$ of cardinality 2 (Example 5.11). We conclude this paper with the following natural open question.

**Question 5.12.** Let $R$ be an integral domain. For which nonempty subsets $S$ of $R$ does the following property hold: the ring $\text{Int}(S, R)$ is an idf-domain if and only if $R$ is an IFD?
